The chef in our place is sloppy, and when he prepares a stack of pancakes they come out all different sizes. Therefore, when I deliver them to a customer, on the way to the table I rearrange them so that the smallest winds up on top, and so on, down to the largest at the bottom, by grabbing several from the top and flipping them over, repeating this varying the number I flip, as many times as necessary. If there are n pancakes, what is the maximum number of flips as a function of n, that I will ever have to use to rearrange them?

Trivial Bounds Algorithm for upper bound Lower Bound Burnt Pancakes

Trivial Bounds

- lower bound: for $n \ge 4$, $f(n) \ge n$
- M.R. Garey et. al.showed that $f(n) \ge n + 1$ for $n \ge 6$.
- upper bound: $f(n) \leq 2n$.

Trivial Bounds Algorithm for upper bound Lower Bound Burnt Pancakes

◆□> ◆□> ◆豆> ◆豆> ・豆 ・ のへで

• They showed that $f(n) \le (5n+5)/3$ by designing an algorithm.

Trivial Bounds Algorithm for upper bound Lower Bound Burnt Pancakes

Some Notation

- flip: taking some pancakes from the top and flipping them over.
- adjacency: a pair of pancakes that are adjacent in the stack, and no other pancake has size intermediate between the two. (It is assumed that the first and the last pancakes are adjacent)
- block: adjacency closure
- free: if a pancake is not in a block, it is free.
- *S_n*: Set of possible permutations for a pancake problem of size n.

- 7 t is in a block with last element t+k*o(k>0), t-o is the last element of another block and t+(k+1)*o is ina block. Perform the sequence of flippings shown in fig 2(h) or 2(k) (depending on whether t+(k+1)*o is at the beginning or at the end of its block.)
- 8 none of the above, σ has n-1 adjacencies; halt.

Trivial Bounds Algorithm for upper bound Lower Bound Burnt Pancakes

◆□▶ ◆□▶ ◆三▶ ◆三▶ ◆□ ◆ ○ ◆

Proof of Correctness

Theorem: Algorithm (A) creates a permutation with n-1 adjacencies by at most (5n-7)/3 moves. **Proof:**

- If we have a permutation *σ* with less than n-1 adjacencies, on e of the firs seven cases is applicable. Thus, the algorithm does not stop unless n-1 adjacencies have been created.
- The algorithm will terminate, because at each iteration of the main loop, at least one new adjacency is created and none is destroyed. It remains to prove that the algorithm takes at most (5n-7)/3 moves.

Trivial Bounds Algorithm for upper bound Lower Bound Burnt Pancakes

<ロ> <同> <同> < 回> < 回> < 回> < 回> < 回> < 回</p>

Call: action of case 1 -> action 1 action of case 2 -> action 2 action of case 3 & 6 -> action 3 action of case 4 -> action 4 action of case 5 -> action 5 action of case 7 -> action 7 Then, total number of moves is given by:

$$z = x_1 + x_2 + 4x_3 + x_4 + 2x_5 + x_7$$

Trivial Bounds Algorithm for upper bound Lower Bound Burnt Pancakes

イロト イポト イヨト イヨト 一座

The top of the stack before the flipping and the element next to t-**o** may be either:

- be non-adjacent
- Iorm a new block
- merge a block with a singleton
- erge two blocks

We distinguosh among those cases by adding another index to x_3 . So the total number of adjacencies in the conclusion of the algorithm is:

$$n-1 = a + x_1 + x_2 + 2x_31 + 3x_32 + 3x_33 + 3x_34 + x_4 + x_5 + x_7$$

(1)

Also, if we define b as the number of blocks in π , because each move increases or decreases the number of blocks as in table 2, then:

$$b + x_1 - x_3 1 - x_3 3 - 2x_3 4 - x_5 - x_7 = 1$$

(2) Because $b \le a$, (1) becomes:

 $x_1 + x_2 + 2x_31 + 3x_32 + 3x_33 + 3x_34 + x_4 + x_5 + x_7 + b \le n - 1$

They maximize z subject to (2) and (3) and they show from duality by exhibiting a feasible solution to the dual and primal problem, and get the bound (5n-7)/3.

Let $\tau = 17536428$, and let τ_k denote the sequence $1_k 7_k 5_k 3_k 6_k 4_k 2_k 8_k$, where $m_k = m + (k - 1) * 8$ Consider the permutation $\chi = \tau_1 \tau_2^R \tau_3 \tau_4^R \dots \tau_{m-1} \tau_m^R$, where m is an even integer, and $n = |\chi| = 8^*m$. **Theorem:** $19n/16 \le f(x) \le 17n/16$. **Scetch of Proof:** $\chi \rightarrow \tau_2 \tau_1^R \tau_3 \dots \rightarrow \tau_2^R \tau_1^R \tau_3 \dots \rightarrow \tau_1 \tau_2 \tau_3$ Thus in 3n/16 moves, we get $1_k 2_k 3_k 4_k 5_k 6_k 7_k 8_k$. Also, each τ

can be ordered in 8 steps, thus the upper bound established.

Trivial Bounds Algorithm for upper bound Lower Bound Burnt Pancakes

◆□▶ ◆□▶ ◆三▶ ◆三▶ ・三 ・ のへで

k-stable: a move is k-stable if it contains a substring of the form $1_k 7_k \sigma 2_k 8_k$ (or its reverse) **event:** χ_j is an event if χ_{j-1} is k-stable for some k, but χ_j , $\chi_{j+1},...,\chi_{f(\chi)}$ are not. **Claim 1:** There are exactly m events. **Claim 2:** $f(\chi) \ge n + w$. **Claim 3:** $\forall j$, $1 \le j \le m - 1$, there exists a waste χ_l with $i_j \le l \le i_{j+1}$ Thus $f(\chi) \ge n + w \ge n + \frac{m}{2} = 17n/16$. Introduction Bill's Paper Sorting an instance Sorting an instance

• They showed $3n/2-1 \le f(n) \le 2n+3$.

Hardness Model #1 Model #2

- Sorting pancakes seems to be \mathcal{NP} -Complete
- Sorting by exchanging is easy Selection Sort
- Caprara: Sorting by reversals is \mathcal{NP} -Complete.
- Sorting *n* pancakes which can take only *k* different sizes is:

◆□▶ ◆□▶ ◆三▶ ◆三▶ ● ● ●

- Easy for *k* = 2
- For *k* > 2?
- Heydari and Sudborough: $3SAT \leq_{p} PSP$

Hardness Model #1 Model #2

PSP:

- *Instance* : A permutation π of $1, 2, \ldots, n, n \ge 1$.
- Question : Is it possible to transform π into a permutation π' such that $\pi'(1) = n$ by a sequence of prefix reversals each creating an adjacency without destroying any existing adjacencies? ($\pi'(1) = n$ means that the first element is *n*.)
