Outline

Motivation

Exact SQP

Inexact SQP

Summary
Two topics of this talk

1. Fill in a gap in algorithmic development for smaller-scale problems.

## Two contributions

1. **Sequential quadratic optimization method with fast infeasibility detection**
   - Guaranteed progress towards (linearized) feasibility each iteration
   - Carefully constructed update of a penalty parameter
   - Separate multipliers for feasibility and optimality
   - Global and fast local convergence for both feasible and infeasible problems

2. **Active-set method with inexact step computations for large-scale problems**
   - Framework extended from method above
   - Allows generic inexact solution of subproblems
   - Careful control of semi-smooth residual functions
   - Global and fast local convergence (at least, that’s the plan!)
Outline

Motivation

Exact SQP

Inexact SQP

Summary
Constrained optimization

Suppose that our optimization problem (OP) is infeasible:

- modeling errors
- data inconsistency
- perturbed/added constraints

Then, we want to solve a feasibility problem (FP).

Many algorithms/codes do this already, either by

- switching back-and-forth
- transitioning (via penalization)
Main contribution (Part 1)

Active-set method that completes the convergence picture for nonlinear optimization:

Sequential quadratic optimization (SQO)

Compute direction $d$ and multipliers $(y, z)$ for (OP) by solving

$$
\begin{align*}
\min_d & \quad f_k + g_k^T d + \frac{1}{2} d^T H_k d \\
\text{s.t.} & \quad c_k + J_k^T d = 0, \quad x_k + d \geq 0.
\end{align*}
$$

where

$$
\begin{align*}
g(x) & := \nabla f(x), \\
J(x) & := \nabla c(x),
\end{align*}
$$

and

$$
H(x, y, z, \mu) \approx \nabla^2_{xx} F(x, y, z, \mu).
$$

Observe:

- May reduce to Newton’s method if active set is identified.
- However, a globalization mechanism is needed.
- Moreover, this subproblem may be infeasible!
Recent literature

- (Rich history of SQO methods)
- Fletcher, Leyffer (2002)
- Byrd, Gould, Nocedal (2005)
- Byrd, Nocedal, Waltz (2008)
- Byrd, Curtis, Nocedal (2010)
- Gould, Robinson (2010)
Issue faced by all optimization solvers

Move towards feasibility and/or objective decrease?

\[ x_k \]

\[ \text{opt. = obj. + feas.} \]

\[ \text{feas.} \]

You choose
FILTER and steering strategies

- FILTER: “... we make use of a property of the phase I algorithm in our QP solver. If an infeasible QP is detected, [a feasibility restoration phase is entered].”

- Steering methods solve a sequence of constrained subproblems:

$$x_k$$

opt. = obj. + feas.  
feas.
Our approach: Two-phase strategy

- “Feasibility step” to determine possible progress toward feasibility.
- “Optimality step” exploits information obtained by “feasibility step”.

- Objective function never ignored (unlike FILTER).
- At most two subproblems solved per iteration (unlike steering).
- Reduces to SQO for optimization problem in feasible cases.
- Reduces to (perturbed) SQO for feasibility problem in infeasible cases.
Ensuring global convergence

1. Compute feasibility step $\overline{d}_k$ to determine highest level of feasibility improvement.
2. Compute optimality step $\hat{d}_k$.
3. Set $d_k \leftarrow \tau_k \hat{d}_k + (1 - \tau_k)d_k$ to obtain proportional feasibility improvement.
4. Update penalty parameter to ensure sufficient decrease in a merit function.
Feasibility step

(1) Compute feasibility step $\overline{d}_k$.

- Solve for $(\overline{d}_k, \overline{r}_k, \overline{s}_k, \overline{t}_k)$ and $(\overline{y}^E_{k+1}, \overline{z}^T_{k+1})$:

$$
\min_{d,r,s,t} e^T(r + s) + e^T t + \frac{1}{2} d^T H_k d \\
\text{s.t.} \quad \begin{cases}
  c_k + J_k^T d = r - s \\
  x_k + d \geq -t \\
  (r, s, t) \geq 0.
\end{cases}
$$

Resulting $\overline{d}_k$ yields a reduction in a local model of $\nu$:

$$l_k(d) := \left\| \begin{bmatrix} c_k + J_k^T d \\ \min \{ x_k + d, 0 \} \end{bmatrix} \right\|_1.$$

That is, it yields

$$\Delta l_k(\overline{d}_k) = l_k(0) - l_k(\overline{d}_k) \geq 0.$$
Optimality step

(OP):
\[
\min_x f(x) \\
\text{s.t. } c(x) = 0, \ x \geq 0
\]

(FP):
\[
\min_x v(x)
\]
where
\[
v(x) := \left\| \begin{bmatrix} c(x) \\ \min \{x, 0\} \end{bmatrix} \right\|_1
\]

(PP):
\[
\min_x \phi(x, \mu)
\]
where
\[
\phi(x, \mu) := \mu f(x) + v(x)
\]

(FJ):
\[
\mathcal{F}(x, y, z, \mu) := \\
\mu f(x) + y^T c(x) - z^T x
\]

(2) Compute optimality step \( \hat{d}_k \).

- Determine \( \mathcal{E}_k \) and \( \mathcal{I}_k \) for which \( \overline{d}_k \) is linearly feasible:
\[
c_k^\mathcal{E}_k + J_k^\mathcal{E}_k^T \overline{d}_k = 0, \ x_k^\mathcal{I}_k + \overline{d}_k^\mathcal{I}_k \geq 0.
\]

- Solve for \( (\hat{d}_k, \hat{r}^\mathcal{E}_k, \hat{s}^\mathcal{E}_k, \hat{t}^\mathcal{I}_k) \) and \( (\hat{y}^\mathcal{E}_{k+1}, \hat{z}^\mathcal{I}_{k+1}) \):
\[
\min_{d, r^\mathcal{E}_k, s^\mathcal{E}_k, t^\mathcal{I}_k} \mu_k g_k^T d + e^T (r^\mathcal{E}_k + s^\mathcal{E}_k) + e^T t^\mathcal{I}_k + \frac{1}{2} d^T \hat{H}_k d
\]

\[
\begin{cases}
\begin{align*}
& c_k^\mathcal{E}_k + J_k^\mathcal{E}_k^T d = 0 \\
& c_k^\mathcal{E}_k + J_k^\mathcal{E}_k^T d = r^\mathcal{E}_k - s^\mathcal{E}_k \\
& x_k^\mathcal{I}_k + d^\mathcal{I}_k \geq 0 \\
& x_k^\mathcal{I}_k + d^\mathcal{I}_k \geq -t^\mathcal{I}_k \\
& (r^\mathcal{E}_k, s^\mathcal{E}_k, t^\mathcal{I}_k) \geq 0.
\end{align*}
\end{cases}
\]
Search direction

\[ (OP): \quad \min_x f(x) \]
\[ \text{s.t. } c(x) = 0, \ x \geq 0 \]

\[ (FP): \quad \min_x \nu(x) \]
where
\[ \nu(x) := \begin{bmatrix} c(x) \\ \min\{x, 0\} \end{bmatrix}_1 \]

\[ (PP): \quad \min_x \phi(x, \mu) \]
where
\[ \phi(x, \mu) := \mu f(x) + \nu(x) \]

\[ (FJ): \quad \mathcal{F}(x, y, z, \mu) := \mu f(x) + y^T c(x) - z^T x \]

(3) Set \( d_k \leftarrow \tau_k \hat{d}_k + (1 - \tau_k) \overline{d}_k \).

- Choose \( \beta \in (0, 1) \).
- Find largest \( \tau_k \in [0, 1] \) such that \( d_k \) satisfies
\[ \Delta l_k(d_k) \geq \beta \Delta l_k(\overline{d}_k). \]
**μ update**

**OP:**
\[
\min_x f(x) \\
\text{s.t. } c(x) = 0, \ x \geq 0
\]

**FP:**
\[
\min_x v(x)
\]
where
\[
v(x) := \left\| \left[ \begin{array}{c} c(x) \\ \min \{x, 0\} \end{array} \right] \right\|_1
\]

**PP:**
\[
\min_x \phi(x, \mu)
\]
where
\[
\phi(x, \mu) := \mu f(x) + v(x)
\]

**FJ:**
\[
\mathcal{F}(x, y, z, \mu) := \\
\mu f(x) + y^T c(x) - z^T x
\]

(4) Update penalty parameter to ensure sufficient decrease.

- Set \(\mu_{k+1}\) so that
  \[
  \mu_{k+1} \leq \frac{1}{\| (\hat{y}_{k+1}, \hat{z}_{k+1}) \|_{\infty}}.
  \]

- Let
  \[
  m_k(d, \mu) = \mu (f(x_k) + g_k^T d) + l_k(d),
  \]
then set \(\mu_{k+1}\) so that \(d_k\) yields
  \[
  \Delta m_k(d_k, \mu_{k+1}) \geq \epsilon \Delta l_k(d_k).
  \]

This ensures sufficient decrease in \(\phi(\cdot, \mu_{k+1})\) from \(x_k\).
Ensuring global convergence

(1) Determine potential level of feasibility improvement:
\[ \Delta l_k(\bar{d}_k) \geq 0. \]

(2) Compute search direction satisfying
\[ \Delta l_k(d_k) \geq \beta \Delta l_k(\bar{d}_k). \]

(3) Update penalty parameter (if necessary) so that
\[ \Delta m_k(d_k, \mu_{k+1}) \geq \epsilon \Delta l_k(d_k). \]

(4) Perform line search on \( \phi(\cdot, \mu_{k+1}) \) at \( x_k \) along the descent direction \( d_k \).
Ensuring fast local convergence: Feasible case

If (OP) is feasible, then:

(a) (QO1) eventually produces linearly feasible directions
(b) $\mu$ eventually remains constant
(c) (QO2) reduces to a standard SQO subproblem

$$\min_{d, r_{E_k}^c, s_{E_k}^c, t_{I_k}^c} \mu_k g_k^T d + e^T (r_{E_k}^c + s_{E_k}^c) + e^T t_{I_k}^c + \frac{1}{2} d^T \hat{H}_k d$$

$$\begin{aligned}
& c_{E_k}^c + J_{E_k}^T d = 0 \\
& c_{I_k}^c + J_{I_k}^T d = r_{E_k}^c - s_{E_k}^c \\
& x_{I_k}^c + d_{I_k} \geq 0 \\
& x_{I_k}^c + d_{I_k} \geq -t_{I_k}^c \\
& (r_{E_k}^c, s_{E_k}^c, t_{I_k}^c) \geq 0.
\end{aligned}$$

(QO2)
Ensuring fast local convergence: Infeasible case

If (OP) is infeasible, then:

(a) (QO1) eventually yields small improvement towards feasibility

(b) \( \mu \to 0 \) and \((\hat{y}_k, \hat{z}_k) \to (\overline{y}_k, \overline{z}_k): \)

\[ \text{If } v_k \neq 0 \text{ and } \Delta l_k(\overline{d}_k) \leq \theta v_k, \text{ then } \]

\[ \mu_k \leq KKT_{inf}(x_k, \overline{y}_{k+1}, \overline{z}_{k+1})^2 \]

\[ \| (\hat{y}_k, \hat{z}_k) - (\overline{y}_k, \overline{z}_k) \| \leq KKT_{inf}(x_k, \overline{y}_{k+1}, \overline{z}_{k+1})^2. \]

(c) (QO2) reduces to (QO1) (i.e., SQO for feasibility)
SQuID

Sequential Quadratic Optimization with Fast Infeasibility Detection

1. Compute feasibility step via (QO1).
2. Check whether infeasible stationary point has been obtained.
3. Update $\mu_k$, $\hat{y}_k$, and $\hat{z}_k$, if necessary (for fast local convergence).
4. Compute optimality step via (QO2).
5. Check whether optimal solution has been obtained.
6. Compute combination of feasibility and optimality steps (for global convergence).
7. Update $\mu_k$, if necessary (for global convergence).
8. Perform line search to obtain decrease in merit function.
Global convergence

Assumptions:

1. The problem functions $f$ and $c$ and their first-order derivatives are bounded and Lipschitz continuous in a convex set containing $\{x_k\}$.

2. There exist $\mu_{\text{max}} \geq \mu_{\text{min}} > 0$ such that, for any $d$,

$$
\mu_{\text{min}} \|d\|^2 \leq d^T \bar{H}_k d \leq \mu_{\text{max}} \|d\|^2
$$

$$
\mu_{\text{min}} \|d\|^2 \leq d^T \hat{H}_k d \leq \mu_{\text{max}} \|d\|^2.
$$

Theorem

Either all limit points of $\{x_k\}$ are feasible or all are infeasible stationary.

Theorem

If $\mu_k \geq \mu_*$ for some $\mu_* > 0$ for all $k$, then every feasible limit point is a KKT point.

Theorem

Suppose $\mu_k \to 0$ and let $K_\mu$ be the subsequence of iterations during which the penalty parameter $\mu_k$ is decreased. Then, if all limit points of $\{x_k\}$ are feasible, then all limit points of $\{x_k\}_{k \in K_\mu}$ correspond to Fritz John points for (OP) where MFCQ fails.
Local convergence: Assumptions

(1) $f$ and $c$ and their first and second derivatives are bounded and Lipschitz continuous in an open convex set containing a given point of interest $x_*$. 

(2) If $(x_*, y_*, z_*)$ is a KKT point for (FP), then
   (a) $J_{Z*} \cup A_*^T$ has full row rank.
   (b) $-e < y_{Z*} < e$ and $0 < z_{A*} < e$.
   (c) $d^T H_* d > 0$ for all $d \neq 0$ such that $J_{Z*} \cup A_*^T d = 0$.

(3) If $(x_*, \tilde{y}_*, \tilde{z}_*, \mu_*)$ is a KKT point for (OP), then (2) holds, $\mu_k \to \mu_* > 0$, and
   (a) $\tilde{z}_{A*} + c_{A*} > 0$.
   (b) $d^T \tilde{H}_* d > 0$ for all $d \neq 0$ such that $J_{E*} \cup A_*^T d = 0$. 

Local convergence

**Theorem**

If \( v^* > 0 \), and \((x_k, y_k, z_k)\) and \((\hat{x}_k, \hat{y}_k, \hat{z}_k)\) are each close to \((x^*, y^*, z^*)\), then

\[
\begin{align*}
\left\| \begin{bmatrix} x_{k+1} - x^* \\ \hat{y}_{k+1} - \hat{y}^* \\ \hat{z}_{k+1} - \hat{z}^* \end{bmatrix} \right\|^2 & \leq C \left\| \begin{bmatrix} x_k - x^* \\ \hat{y}_k - \hat{y}^* \\ \hat{z}_k - \hat{z}^* \end{bmatrix} \right\|^2 + O \left( \left\| \begin{bmatrix} \hat{y}_k - \hat{y}^* \\ \hat{z}_k - \hat{z}^* \end{bmatrix} \right\| \right) + O(\mu)
\end{align*}
\]

for some constant \( C > 0 \) independent of \( k \).

**Theorem**

If \((x_k, y_k, z_k)\) is close to \((x^*, y^*, z^*)\) and \((x_k, y_k, z_k)\) is close to \((x^*, y^*, z^*)\), then

\[
\begin{align*}
\left\| \begin{bmatrix} x_{k+1} - x^* \\ \hat{y}_{k+1} - \hat{y}^* \\ \hat{z}_{k+1} - \hat{z}^* \end{bmatrix} \right\|^2 & \leq C \left\| \begin{bmatrix} x_k - x^* \\ \hat{y}_k - \hat{y}^* \\ \hat{z}_k - \hat{z}^* \end{bmatrix} \right\|^2
\end{align*}
\]

for some constant \( C > 0 \) independent of \( k \).
Numerical experiments: Feasible optimization problems

FILTER: 9 “failures” due to declaration of infeasibility
Others: ≤ 2 “failures” due to declaration of infeasibility
SQuID: Lack of robustness due to lack of SOC and simplistic handling of nonconvexity
Numerical experiments: Infeasible optimization problems
Outline

Motivation

Exact SQP

Inexact SQP

Summary
Large-scale optimization

You’re thinking to yourself:

▶ SQO is expensive enough with **one** subproblem to solve.
▶ You want me to solve **two**?!

Our response:

▶ Allowing **inexactness** gives flexibility in the subproblem solves.
▶ Any work to solve one subproblem is better split between our two.
Optimality conditions

(PP):
\[ \min_x \phi(x, \mu) \text{ s.t. } x \geq 0 \]
where
\[ \phi(x, \mu) := \mu f(x) + v(x) \]

(FP):
\[ \min_x v(x) \text{ s.t. } x \geq 0 \]
where
\[ v(x) := \|c(x)\|_1 \]

Optimality conditions for both (PP) and (FP) involve
\[
\rho(x, y, \mu) := \begin{bmatrix}
\min\{\mu g(x) + J(x)y, x\} \\
\min\{[c(x)]^+, e - y\} \\
\min\{[c(x)]^-, e + y\}
\end{bmatrix}
\]
where
\[ [c(x)]^+ := \max\{c(x), 0\} \]
and \[ [c(x)]^- := \max\{-c(x), 0\}. \]

Observe:
- If \( \rho(x, y, \mu) = 0 \), \( v(x) = 0 \), and \( \mu > 0 \), then \((x, y/\mu)\) is a KKT point for (OP).
- If \( \rho(x, y, \mu) = 0 \), \( v(x) > 0 \), and \( \mu = 0 \), then \( x \) is an infeasible stationary point.
Two subproblems

Define the model of $\phi(\cdot, \mu)$ at $x_k$ given by

$$m_k(d, \mu) := \mu(f_k + g_k^T d) + \|c_k + J_k d\|_1.$$ 

We iterate by (approximately) solving two subproblems:

- **Feasibility subproblem:**
  $$\min_d -\Delta m_k(d, 0) + \frac{1}{2} d^T \hat{H}_k d \text{ s.t. } x_k + d \geq 0. \quad (QO1)$$

- **Optimality subproblem:**
  $$\min_d -\Delta m_k(d, \mu_k) + \frac{1}{2} d^T \hat{H}_k d \text{ s.t. } x_k + d \geq 0. \quad (QO2)$$

Optimality conditions for both (QO1) and (QO2) involve

$$\rho_k(d, y, \mu, H) := \begin{bmatrix} \min\{\mu g_k + Hd + J_k y, x_k + d\} \\
\min\{[c_k + J_k^T d]^+, e - y\} \\
\min\{[c_k + J_k^T d]^-, e + y\} \end{bmatrix}.$$
Main contribution (Part 2)

Active-set method that allows generic inexact subproblem solves:

- “Termination tests” dictate when an inexact solution is acceptable.
- Tests primarily monitor the reductions
  \[ \Delta m_k(\bar{d}_k, 0) \quad \text{and} \quad \Delta m_k(\hat{d}_k, \mu_k) \]
  and the residuals
  \[ \rho_k(\bar{d}_k, \bar{y}_{k+1}, 0, \bar{H}_k) \quad \text{and} \quad \rho_k(\hat{d}_k, \hat{y}_{k+1}, \mu_k, \hat{H}_k). \]

- Essentially, these ensure primal and dual convergence, respectively.
- (“Exact case”: residuals are always zero, so we focused on model reductions.)
Termination test 1: High-level

The primal-dual pairs \((\bar{d}_k, \bar{y}_{k+1})\) and \((\hat{d}_k, \hat{y}_{k+1})\) are acceptable if

- the feasibility step
  - yields a nontrivial reduction in the feasibility model
  - the error in solving (QO1) is small compared to the error in solving (FP)
- the optimality step
  - yields a nontrivial reduction in the penalty function model
  - the error in solving (QO2) is small compared to the error in solving (PP)
- and, in addition,
  - the optimality step yields proportional improvement in the feasibility model.
Termination test 1: Low-level

The primal-dual pairs \((\bar{d}_k, \bar{y}_{k+1})\) and \((\hat{d}_k, \hat{y}_{k+1})\) are acceptable if

- the feasibility step satisfies

\[
\Delta m_k(\bar{d}_k, 0) \geq \theta \|\bar{d}_k\|^2 > 0
\]
\[
\|\rho_k(\bar{d}_k, \bar{y}_{k+1}, 0, \bar{H}_k)\| \leq \kappa \|\rho(x_k, \bar{y}_k, 0)\|
\]

- the optimality step satisfies

\[
\Delta m_k(\hat{d}_k, \mu_k) \geq \theta \|\hat{d}_k\|^2 > 0
\]
\[
\|\rho_k(\hat{d}_k, \hat{y}_{k+1}, \mu_k, \hat{H}_k)\| \leq \kappa \|\rho(x_k, \hat{y}_k, \mu_k)\|
\]

- and, in addition,

\[
\Delta m_k(\hat{d}_k, \mu_k) \geq \epsilon \Delta m_k(\bar{d}_k, 0)
\]

where \(\theta > 0\), \(\kappa \in (0, 1)\), and \(\epsilon \in (0, 1)\) are user-defined constants.
Termination test 2: High-level

The primal-dual pairs \((\bar{d}_k, \bar{y}_{k+1})\) and \((\hat{d}_k, \hat{y}_{k+1})\) are acceptable if

- the feasibility step
  - yields a nontrivial reduction in the feasibility model
  - the error in solving \((QO1)\) is small compared to the error in solving \((FP)\)
- the optimality step
  - yields a nontrivial reduction in the penalty function model
  - the error in solving \((QO2)\) is small compared to the error in solving \((FP)\)
- and, in addition, we
  - take a convex combination of the steps for proportional improvement toward feasibility
  - (potentially) decrease the penalty parameter.
Termination test 2: Low-level

The primal-dual pairs \((\overline{d}_k, \overline{y}_{k+1})\) and \((\widehat{d}_k, \widehat{y}_{k+1})\) are acceptable if

- the feasibility step satisfies
  \[
  \Delta m_k(\overline{d}_k, 0) \geq \theta \| \overline{d}_k \|^2 > 0
  \]
  \[
  \| \rho_k(\overline{d}_k, \overline{y}_{k+1}, 0, \overline{H}_k) \| \leq \kappa \| \rho(x_k, \overline{y}_k, 0) \|
  \]

- the optimality step satisfies
  \[
  \Delta m_k(\widehat{d}_k, \mu_k) \geq \theta \| \widehat{d}_k \|^2 > 0
  \]
  \[
  \| \rho_k(\widehat{d}_k, \widehat{y}_{k+1}, \mu_k, \widehat{H}_k) \| \leq \kappa \| \rho(x_k, \widehat{y}_k, \mu_k) \|
  \]

- and, in addition,
  \[
  d_k \leftarrow \tau_k \widehat{d}_k + (1 - \tau_k) \overline{d}_k \quad \text{so that } \Delta m_k(d_k, 0) \geq \epsilon \Delta m_k(\overline{d}_k, 0)
  \]
  \[
  \mu_{k+1} \leftarrow \begin{cases} \mu_k & \text{if } \Delta m_k(d_k, \mu_k) \geq \beta \Delta m_k(d_k, 0) \\ \min \left\{ \delta \mu_k, \frac{(1 - \beta) \Delta m_k(d_k, 0)}{g_k^T d_k + \theta \| d_k \|^2} \right\} & \text{otherwise} \end{cases}
  \]

where \(\theta > 0, \kappa \in (0, 1), \epsilon \in (0, 1), \beta \in (0, 1),\) and \(\delta \in (0, 1)\) are constants.
Termination test 3: High-level

The primal-dual pairs $(\hat{d}_k, \hat{y}_{k+1})$ and $(\hat{d}_k, \hat{y}_{k+1})$ are acceptable if

- the feasibility step is zero
- the optimality step is zero
- the feasibility multipliers are not changed
- and, in addition,
  - the error in solving (QO2) is small compared to the error in solving (PP)
Termination test 3: Low-level

The primal-dual pairs \((\overline{d}_k, \overline{y}_{k+1})\) and \((\hat{d}_k, \hat{y}_{k+1})\) are acceptable if

- \(\overline{d}_k \leftarrow 0\)
- \(\hat{d}_k \leftarrow 0\)
- \(\overline{y}_{k+1} \leftarrow \overline{y}_k\)
- and, in addition,

\[
\|\rho_k(0, \hat{y}_{k+1}, \mu_k, \hat{H}_k)\| \leq \kappa \|\rho(x_k, \hat{y}_k, \mu_k)\|
\]

where \(\kappa \in (0, 1)\) is a constant.
Inexact SQO

(1) Check whether infeasible stationary point or optimal solution obtained.
(2) Compute optimality and feasibility steps so that TT1, TT2, or TT3 holds.
   ▶ Hessian modifications performed within subproblems solves.
(3) Update $\bar{y}_k$, and $\hat{y}_k$, if necessary (details suppressed).
(4) Compute combination of feasibility and optimality steps.
(5) Update $\mu_k$, if necessary.
(5) Perform line search to obtain decrease in merit function.
Global convergence: Assumptions

1. The problem functions $f$ and $c$ and their first-order derivatives are bounded and Lipschitz continuous in a convex set containing $\{x_k\}$.

2. $\{H_k\}$ and $\{\hat{H}_k\}$ are bounded.

3. If $x_k$ is stationary for the penalty problem, then the subproblem solver eventually produces a direction of insufficient curvature or $y$ such that $\rho_k(0, y, \mu_k, \hat{H}_k)$ is arbitrarily small. Else, it eventually produces a direction of insufficient curvature or $(d, y)$ such that $\Delta m_k(d, \mu_k) \geq \theta \|d\|^2$ with $\rho_k(d, y, \mu_k, \hat{H}_k)$ arbitrarily small.

4. For the feasibility subproblem, the subproblem solver eventually produces a direction of insufficient curvature or, for $\xi_k > 0$, it produces $(d, y)$ satisfying $\max\{\xi_k, \Delta m_k(d, 0)\} \geq \theta \|d\|^2$ with $\rho_k(d, y, 0, H_k)$ arbitrarily small.
Global convergence

**Theorem**
*The following limit always holds:*

\[
\lim_{k \to \infty} \| \rho(x_k, y_k, 0) \| = 0.
\]

**Theorem**
*The following limit holds if \( \mu_k = \mu > 0 \) for all large \( k \):*

\[
\lim_{k \to \infty} \| \rho(x_k, \hat{y}_k, \mu) \| = 0.
\]

**TO DO:**
- Ensure that \( \mu \) stays bounded below under “nice” conditions.
- Local convergence(?!)

Motivation

Exact SQP

Inexact SQP

Motivation

Exact SQP

Inexact SQP

Summary
Summary

- Developed an SQO method that completes the convergence picture for NLO:

<table>
<thead>
<tr>
<th>Problem type</th>
<th>Global convergence</th>
<th>Fast local convergence</th>
</tr>
</thead>
<tbody>
<tr>
<td>Feasible</td>
<td>✓</td>
<td>✓</td>
</tr>
<tr>
<td>Infeasible</td>
<td>✓</td>
<td>✓</td>
</tr>
</tbody>
</table>

- Proposed extensions for solving large-scale problems with inexact calculations.
Thanks!!

Infeasibility detection:

Inexactness and constrained optimization:
