# The Feasibility Pump

Matteo Fischetti, Fred Glover and Andrea Lodi, *The Feasibility Pump*, Math. Programming. Ser A (March 2005)

# Introduction

- Finding a feasible solution for MIP is NP-Hard and is difficult in practice for some important models and applications.
- Other successful primal heuristics like RINS and Local Branching can be used only if an initial feasible solution is known.
- The earlier a feasible solution is found, the better...

- We consider a generic MIP of the following form:

$$\begin{aligned} \min \quad & c^T x \\ & Ax \geq b \\ & x_j \text{ integer} \quad \forall j \in \mathbb{I} \end{aligned}$$

- The authors intend to find a feasible solution for the problem.

- Let  $P := \{x : Ax \geq b\}$  denote the polyhedron associated with the LP relaxation of the given MIP.
- The rounding  $\tilde{x}$  of  $x$  is obtained by setting  $\tilde{x}_j := \lfloor x_j \rfloor$  if  $j \in \mathbb{I}$  and  $\tilde{x}_j := x_j$  otherwise.
- The  $L_1$ -norm distance between a generic point  $x \in P$  and a given integer point  $\tilde{x}$  is defined as:

$$\Delta(x, \tilde{x}) = \sum_{j \in \mathbb{I}} |x_j - \tilde{x}_j|$$

- The distance function may then be written as:

$$\Delta(x, \tilde{x}) = \sum_{j \in I: \tilde{x}_j = l_j} (x_j - l_j)^+ + \sum_{j \in I: \tilde{x}_j = u_j} (u_j - x_j)^+ + \sum_{j \in I: l_j < \tilde{x}_j < u_j} (x_j^+ + x_j^-)$$

with

$$x_j = \tilde{x}_j + x_j^+ - x_j^-, \quad x_j^+, x_j^- \geq 0, \forall j \in I : l_j < \tilde{x}_j < u_j$$

- for mixed 0-1 programs, the additional variables are not needed.
- Given an integer point  $\tilde{x}$ , the closest point  $x^* \in P$  can be determined by solving the LP

$$\min\{\Delta(x, \tilde{x}) : Ax \geq b\}$$

# The basic scheme

- We start with any  $x^* \in P$  and define its rounding  $\tilde{x}$
- At each iteration we look for a point  $x^* \in P$  which is closest to the current  $\tilde{x}$  by solving the problem:

$$\min\{\Delta(x, \tilde{x}) : x \in P\}$$

Assuming the distance function is chosen appropriately, this is an easily solvable LP program.

- If  $\Delta(x, \tilde{x}) = 0$ , then  $x^*$  is a feasible MIP solution and we are done.
- Otherwise, we replace  $\tilde{x}$  with the rounding of  $x^*$  and repeat.

The basic algorithm is stated as follows:

- $x^* := \operatorname{argmin}\{c^T x : Ax \geq b\}$ ;
- if  $x^*$  is integer, return  $x^*$ ;
- Let  $\tilde{x} := [x^*]$  (rounding of  $x^*$ )
- while (time < TL ) do
- compute  $x^* := \operatorname{argmin}\{\Delta(x, \tilde{x}) : Ax \geq b\}$ ;
- if  $x^*$  is integer, return  $x^*$ ;
- if  $\exists j \in \mathbb{I} : [x_j^*] \neq \tilde{x}_j$  then
- $\tilde{x} := [x^*]$
- else
- flip the  $\text{TT} = \text{rand}(T/2, 3T/2)$  entries  $\tilde{x}_j (j \in \mathbb{I})$  with highest  $|x_j^* - \tilde{x}_j|$
- endif
- enddo

- The flipping deals with stalling issues..
- Possibility of Cycling.. A pertubation mechanism is needed
- On detecting a cycle, for each  $j \in \mathbb{I}$  generate a random value  $\rho_j \in [-0.3, 0.7]$  and flip  $\tilde{x}_j$  in case  $|x_j^* - \tilde{x}_j| + \max[\rho_j, 0] > 0.5$
- FP generates two (hopefully convergent) trajectories of points  $x^*$  and  $\tilde{x}$  that satisfies feasibility in a complementary but partial way...

- Improving computing time
- Improving the quality of the heuristic solution.
- FP is also applicable to MINLP problems.

# Notation

- IP:

$$\begin{aligned} & \text{Min } cx, \\ & \text{s.t. } Ax \geq b \\ & x_i \in \{0, 1\}, (i = 1, \dots, n) \end{aligned}$$

- Let:

$$\begin{aligned} K &= \left\{ x \in \mathbb{R}^n : -\frac{e}{2} \leq x \leq \frac{e}{2} \right\}, \\ K^* &= \left\{ x \in \mathbb{R}^n : \|x\|_1 \leq \frac{1}{2}n \right\} \\ &= \left\{ x \in \mathbb{R}^n : \delta x \leq \frac{1}{2}n, \forall \delta \in \{\pm 1\}^n \right\} \end{aligned}$$

- What are the extreme points of  $K$ ?
- What are the facets of  $K^*$ ?
- What is relation between  $K + \frac{1}{2}e$  and  $K^* + \frac{1}{2}e$ ?
- $\frac{1}{2}\delta + \frac{1}{2}e = x$

- What are the extreme points of  $K$ ?
- What are the facets of  $K^*$ ?
- What is relation between  $K + \frac{1}{2}e$  and  $K^* + \frac{1}{2}e$ ?
- $\frac{1}{2}\delta + \frac{1}{2}e = x$

- Geometry of intersection cuts.
- Deepening the cuts
- What happens if degenerate?
- How is it a primal heuristic?

- Let  $\bar{x} = x - \frac{1}{2}e$ .
- $r = \bar{x} + \lambda a, \lambda \geq 0$  is a half line originating at  $\bar{x}$ .
- Let  $\Lambda(\delta)$  be the distance of  $\bar{x}$  from  $\delta$ .
- Then:

$$\begin{aligned}(\bar{x} + \Lambda(\delta)a)\delta &= \frac{1}{2}n \\ \Rightarrow \Lambda(\delta) &= \frac{\frac{n}{2} - \delta\bar{x}}{\delta a} > 0\end{aligned}$$

Let  $I \subset \mathbb{N}$ , and

$$p(\delta, I) = - \sum_{i \in I} \delta_i \bar{x}_i,$$

$$q(\delta, I) = \sum_{i \in I} \delta_i a_i,$$

$$\lambda(\delta, I) = p(\delta, I)/q(\delta, I)$$

$$v(i) = -\frac{\bar{x}_i}{a_i} \quad (i = 1, 2, \dots, n)$$

$$P(\delta) = \frac{n}{2} + p(\delta, \mathbb{N})$$

$$Q(\delta) = q(\delta, \mathbb{N})$$

Note that  $\Lambda(\delta) = \frac{P(\delta)}{Q(\delta)}$

## Decreasing Flip:

$i \in N$  is a decreasing flip if and only if one of the two conditions hold:

- 1  $\delta_i = 1$  and  $v(i) > \Lambda(\delta)$
- 2  $\delta_i = -1$  and  $v(i) < \Lambda(\delta)$

$\delta$  is first reachable if and only if there is no decreasing single flip for  $\delta$ .

After some magical algebraic deductions ...  
Algorithm First Facet

Let  $\delta$  be a reachable facet of  $K^*$ .  
**while** (there is a decreasing flip  $i$  for  $\delta$ )  
    set  $\delta = \delta \diamond i$ .  
**end while**  
**end**
