MINLP

## MINLP Short Course Overview

1. Introduction, Applications, and Formulations
2. Classical Solution Methods
3. Modern Developments in MINLP
4. Implementation and Software

Part I

Introduction, Applications, and Formulations

Leyffer & Linderoth

MINLP

Leyffer & Linderoth

MINLP

## The Problem of the Day

Mixed Integer Nonlinear Program (MINLP)

$$\begin{cases} \text{minimize}_{x,y} & f(x, y) \\ \text{subject to} & c(x, y) \leq 0 \\ & x \in X, y \in Y \text{ integer} \end{cases}$$

- $f, c$  smooth (**convex**) functions
- $X, Y$  polyhedral sets, e.g.  $Y = \{y \in [0, 1]^p \mid Ay \leq b\}$
- $y \in Y$  integer  $\Rightarrow$  hard problem
- $f, c$  *not* convex  $\Rightarrow$  **very** hard problem

## Why the N?

**An anecdote:** July, 1948. A young and frightened George Dantzig, presents his newfangled “linear programming” to a meeting of the Econometric Society of Wisconsin, attended by distinguished scientists like Hotelling, Koopmans, and Von Neumann. Following the lecture, Hotelling<sup>a</sup> pronounced to the audience:

*But we all know the world is nonlinear!*

<sup>a</sup>in Dantzig’s words “a huge whale of a man”

The world is indeed nonlinear

- Physical Processes and Properties
  - Equilibrium
  - Enthalpy
- Abstract Measures
  - Economies of Scale
  - Covariance
  - Utility of decisions

## Why the MI?

- We can use **0-1 (binary) variables** for a variety of purposes
  - Modeling yes/no decisions
  - Enforcing disjunctions
  - Enforcing logical conditions
  - Modeling fixed costs
  - Modeling piecewise linear functions
- If the variable is associated with a physical entity that is **indivisible**, then it must be integer
  1. Number of aircraft carriers to produce. **Gomory’s Initial Motivation**
  2. Yearly number of trees to harvest in Norrland

## A Popular MINLP Method

Dantzig’s Two-Phase Method for MINLP Adapted by Leyffer and Linderoth

1. Convince the user that he or she does not wish to solve a mixed integer nonlinear programming problem at all!
2. Otherwise, solve the continuous relaxation (*NLP*) and round off the minimizer to the nearest integer.
  - **Sometimes** a continuous approximation to the discrete (integer) decision is accurate enough for practical purposes.
    - **Yearly tree harvest in Norrland**
  - For **0 – 1 problems**, or those in which the  $|y|$  is “small”, the continuous approximation to the discrete decision is **not** accurate enough for practical purposes.
  - **Conclusion:** MINLP methods must be studied!

## Example: Core Reload Operation (Quist, A.J., 2000)

- max. reactor efficiency after reload subject to diffusion PDE & safety
- diffusion PDE  $\simeq$  nonlinear equation  $\Rightarrow$  integer & nonlinear model
- avoid reactor becoming **overheated**

## Example: Core Reload Operation (Quist, A.J., 2000)

- look for cycles for moving bundles:  
e.g. 4  $\rightarrow$  6  $\rightarrow$  8  $\rightarrow$  10  
i.e. bundle moved from 4 to 6 ...
- model with binary  $x_{ilm} \in \{0, 1\}$   
 $x_{ilm} = 1$   
 $\Leftrightarrow$  node  $i$  has bundle  $l$  of cycle  $m$

## AMPL Model of Core Reload Operation

Exactly one bundle per node:

$$\sum_{l=1}^L \sum_{m=1}^M x_{ilm} = 1 \quad \forall i \in I$$

AMPL model:

```
var x {I,L,M} binary ;
Bundle {i in I}: sum{1 in L, m in M} x[i,1,m] = 1 ;
```

- **Multiple Choice:** One of the most common uses of IP
- Full AMPL model c-reload.mod at [www.mcs.anl.gov/~leyffer/MacMINLP/](http://www.mcs.anl.gov/~leyffer/MacMINLP/)

## Gas Transmission Problem (De Wolf and Smeers, 2000)

- **Belgium has no gas!**
- All natural gas is imported from Norway, Holland, or Algeria.
- Supply gas to all demand points in a network in a minimum cost fashion.
- Gas is pumped through the network with a series of compressors
- There are constraints on the pressure of the gas within the pipe

## Pressure Loss is Nonlinear

- Assume horizontal pipes and steady state flows
- Pressure loss  $p$  across a pipe is related to the flow rate  $f$  as

$$p_{in}^2 - p_{out}^2 = \frac{1}{\Psi} \text{sign}(f) f^2$$

- $\Psi$ : “Friction Factor”

## Gas Transmission: Problem Input

- Network  $(N, A)$ .  $A = A_p \cup A_a$ 
  - $A_a$ : **active** arcs have compressor. Flow rate can increase on arc
  - $A_p$ : **passive** arcs simply conserve flow rate
- $N_s \subseteq N$ : set of supply nodes
- $c_i, i \in N_s$ : Purchase cost of gas
- $\underline{s}_i, \bar{s}_i$ : Lower and upper bounds on gas “supply” at node  $i$
- $\underline{p}_i, \bar{p}_i$ : Lower and upper bounds on gas pressure at node  $i$
- $s_i, i \in N$ : **supply** at node  $i$ .
  - $s_i > 0 \Rightarrow$  gas added to the network at node  $i$
  - $s_i < 0 \Rightarrow$  gas removed from the network at node  $i$  to meet demand
- $f_{ij}, (i, j) \in A$ : **flow** along arc  $(i, j)$ 
  - $f(i, j) > 0 \Rightarrow$  gas flows  $i \rightarrow j$
  - $f(i, j) < 0 \Rightarrow$  gas flows  $j \rightarrow i$

## Gas Transmission Model

$$\min \sum_{j \in N_s} c_j s_j$$

subject to

$$\begin{aligned} \sum_{j|(i,j) \in A} f_{ij} - \sum_{j|(j,i) \in A} f_{ji} &= s_i \quad \forall i \in N \\ \text{sign}(f_{ij}) f_{ij}^2 - \Psi_{ij} (p_i^2 - p_j^2) &= 0 \quad \forall (i, j) \in A_p \\ \text{sign}(f_{ij}) f_{ij}^2 - \Psi_{ij} (p_i^2 - p_j^2) &\geq 0 \quad \forall (i, j) \in A_a \\ s_i &\in [\underline{s}_i, \bar{s}_i] \quad \forall i \in N \\ p_i &\in [\underline{p}_i, \bar{p}_i] \quad \forall i \in N \\ f_{ij} &\geq 0 \quad \forall (i, j) \in A_a \end{aligned}$$

## Your First Modeling Trick

- Don't include nonlinearities or nonconvexities unless necessary!
- Replace  $p_i^2 \leftarrow \rho_i$

$$\begin{aligned} \text{sign}(f_{ij}) f_{ij}^2 - \Psi_{ij} (\rho_i - \rho_j) &= 0 \quad \forall (i, j) \in A_p \\ f_{ij}^2 - \Psi_{ij} (\rho_i - \rho_j) &\geq 0 \quad \forall (i, j) \in A_a \\ \rho_i &\in [\sqrt{\underline{p}_i}, \sqrt{\bar{p}_i}] \quad \forall i \in N \end{aligned}$$

- This trick only works because
  1.  $p_i^2$  terms appear only in the bound constraints
  2. Also  $f_{ij} \geq 0 \forall (i, j) \in A_a$
- This model is nonconvex:  $\text{sign}(f_{ij}) f_{ij}^2$  is a nonconvex function

## Dealing with sign(·): The NLP Way

- Use auxiliary binary variables to indicate direction of flow
- Let  $|f_{ij}| \leq F \forall (i, j) \in A_p$

$$z_{ij} = \begin{cases} 1 & f_{ij} \geq 0 \\ 0 & f_{ij} \leq 0 \end{cases} \quad \begin{cases} f_{ij} \geq -F(1 - z_{ij}) \\ f_{ij} \leq Fz_{ij} \end{cases}$$

- Note that

$$\text{sign}(f_{ij}) = 2z_{ij} - 1$$

- Write constraint as

$$(2z_{ij} - 1)f_{ij}^2 - \Psi_{ij}(\rho_i - \rho_j) = 0.$$

## Dealing with sign(·): The MIP Way

Model

$$f_{ij} > 0 \Rightarrow \begin{cases} f_{ij}^2 \leq \Psi_{ij}(\rho_i - \rho_j) \\ f_{ij}^2 \geq \Psi_{ij}(\rho_i - \rho_j) \end{cases} \quad f_{ij} < 0 \Rightarrow \begin{cases} f_{ij}^2 \leq \Psi_{ij}(\rho_j - \rho_i) \\ f_{ij}^2 \geq \Psi_{ij}(\rho_j - \rho_i) \end{cases}$$

$$m \leq f_{ij}^2 - \Psi(\rho_i - \rho_j) \leq M \quad l \leq f_{ij}^2 - \Psi(\rho_j - \rho_i) \leq L$$

Example

$$f_{ij} > 0 \Rightarrow z_{ij} = 1 \Rightarrow f_{ij}^2 \leq \Psi(\rho_i - \rho_j)$$

$$f_{ij} > 0 \Rightarrow z_{ij} = 1 \Rightarrow f_{ij}^2 \leq \Psi(\rho_i - \rho_j)$$

$$f_{ij} > 0 \Rightarrow z_{ij} = 1 \Rightarrow f_{ij}^2 \leq \Psi(\rho_i - \rho_j)$$

## Dealing with sign(·): The MIP Way

- Wonderful MIP Modeling reference is [Williams \(1993\)](#)
- If you put it all together you get...

<ul style="list-style-type: none"> <li>• <math>z_{ij} \in \{0, 1\}</math>: Indicator if flow is positive</li> <li>• <math>y_{ij} \in \{0, 1\}</math>: Indicator if flow is negative</li> </ul>	$\begin{aligned} f_{ij} &\leq Fz_{ij} \\ f_{ij} &\geq -Fy_{ij} \\ z_{ij} + y_{ij} &= 1 \\ f_{ij}^2 + Mz_{ij} &\leq M + \Psi_{ij}(\rho_i - \rho_j) \\ f_{ij}^2 + my_{ij} &\geq m + \Psi_{ij}(\rho_i - \rho_j) \\ f_{ij}^2 + Ly_{ij} &\leq L + \Psi_{ij}(\rho_j - \rho_i) \\ f_{ij}^2 + ly_{ij} &\geq l + \Psi_{ij}(\rho_j - \rho_i) \end{aligned}$
--	---

## Special Ordered Sets

- Sven thinks the NLP way is better
- Jeff thinks the MIP way is better
- **Neither way** is how it is done in De Wolf and Smeers (2000).
- Heuristic for finding a good starting solution, then a local optimization approach based on a piecewise-linear simplex method
- Another (similar) approach involves approximating the nonlinear function by piecewise linear segments, but searching for the globally optimal solution: [Special Ordered Sets of Type 2](#)
- If the “multidimensional” nonlinearity cannot be removed, resort to [Special Ordered Sets of Type 3](#)

## Portfolio Management

- $N$ : Universe of asset to purchase
- $x_i$ : Amount of asset  $i$  to hold
- $B$ : Budget

$$\min_{x \in \mathbb{R}_+^{|N|}} \left\{ u(x) \mid \sum_{i \in N} x_i = B \right\}$$

- **Markowitz**:  $u(x) \stackrel{\text{def}}{=} -\alpha^T x + \lambda x^T Q x$ 
  - $\alpha$ : Expected returns
  - $Q$ : Variance-covariance matrix of expected returns
  - $\lambda$ : Risk aversion parameter

## More Realistic Models

- $b \in \mathbb{R}^{|N|}$  of “benchmark” holdings
- **Benchmark Tracking**:  $u(x) \stackrel{\text{def}}{=} (x - b)^T Q (x - b)$ 
  - **Constraint on  $\mathbb{E}$ [Return]**:  $\alpha^T x \geq r$
- **Limit Names**:  $|i \in N : x_i > 0| \leq K$ 
  - Use binary indicator variables to model the implication  $x_i > 0 \Rightarrow y_i = 1$
  - Implication modeled with **variable upper bounds**:

$$x_i \leq B y_i \quad \forall i \in N$$

$$\sum_{i \in N} y_i \leq K$$

## Even More Models

- **Min Holdings**:  $(x_i = 0) \vee (x_i \geq m)$ 
  - Model implication:  $x_i > 0 \Rightarrow x_i \geq m$
  - $x_i > 0 \Rightarrow y_i = 1 \Rightarrow x_i \geq m$
  - $x_i \leq B y_i, x_i \geq m y_i \quad \forall i \in N$
- **Round Lots**:  $x_i \in \{k L_i, k = 1, 2, \dots\}$ 
  - $x_i - z_i L_i = 0, z_i \in \mathbb{Z}_+ \quad \forall i \in N$
- Vector  $h$  of initial holdings
- Transactions:  $t_i = |x_i - h_i|$
- **Turnover**:  $\sum_{i \in N} t_i \leq \Delta$
- **Transaction Costs**:  $\sum_{i \in N} c_i t_i$  in objective
- **Market Impact**:  $\sum_{i \in N} \gamma_i t_i^2$  in objective

## Making “Plays”

- Suppose that the stocks are partitioned into sectors  $S_1 \subseteq N, S_2 \subseteq N, \dots, S_K \subseteq N$
- The Fund Manager wants to invest all money into one sector “play”
  - $\sum_{i \in S_k} x_i > 0 \Rightarrow \sum_{j \in N \setminus S_k} x_j = 0$
- Modeling Choices:
- **Aggregated**:

$$\sum_{i \in S_k} x_i \leq B z_k \quad \sum_{j \in N \setminus S_k} x_j + B z_k \leq B$$

- **Disaggregated**:

$$x_i \leq u_i z_i \quad \forall i \in N \quad x_j + u_j z_i \leq u_j \quad \forall j \mid i \in S_k, j \notin S_k$$

Which is better?: Part III has the answer

## Multiproduct Batch Plants (Kocis and Grossmann, 1988)

- $M$ : Batch Processing Stages
  - $N$ : Different Products
  - $H$ : Horizon Time
  - $Q_i$ : Required quantity of product  $i$
  - $t_{ij}$ : Processing time product  $i$  stage  $j$
  - $S_{ij}$ : "Size Factor" product  $i$  stage  $j$
- 
- $B_i$ : Batch size of product  $i \in N$
  - $V_j$ : Stage  $j$  size:  $V_j \geq S_{ij}B_i \forall i, j$
  - $N_j$ : Number of machines at stage  $j$
  - $C_i$ : Longest stage time for product  $i$ :  $C_i \geq t_{ij}/N_j \forall i, j$

## Multiproduct Batch Plants

$$\min \sum_{j \in M} \alpha_j N_j V_j^{\beta_j}$$

s.t.

$$V_j - S_{ij}B_i \geq 0 \quad \forall i \in N, \forall j \in M$$

$$C_i N_j \geq t_{ij} \quad \forall i \in N, \forall j \in M$$

$$\sum_{i \in N} \frac{Q_i}{B_i} C_i \leq H$$

Bound Constraints on  $V_j, C_i, B_i, N_j$

$$N_j \in \mathbb{Z} \quad \forall j \in M$$

## Modeling Trick #2

- Horizon Time and Objective Function Nonconvex. :- (
- Sometimes variable transformations work!

$$v_j = \ln(V_j), n_j = \ln(N_j), b_i = \ln(B_i), c_i = \ln C_i$$

$$\min \sum_{j \in M} \alpha_j e^{N_j + \beta_j V_j}$$

$$\text{s.t. } v_j - \ln(S_{ij})b_i \geq 0 \quad \forall i \in N, \forall j \in M$$

$$c_i + n_j \geq \ln(\tau_{ij}) \quad \forall i \in N, \forall j \in M$$

$$\sum_{i \in N} Q_i e^{C_i - B_i} \leq H$$

(Transformed) Bound Constraints on  $V_j, C_i, B_i$

## How to Handle the Integrality?

- But what to do about the integrality?

$$1 \leq N_j \leq \bar{N}_j \quad \forall j \in M, N_j \in \mathbb{Z} \quad \forall j \in M$$

- $n_j \in \{0, \ln(2), \ln(3), \dots\}$

$$Y_{kj} = \begin{cases} 1 & n_j \text{ takes value } \ln(k) \\ 0 & \text{Otherwise} \end{cases}$$

$$n_j - \sum_{k=1}^K \ln(k) Y_{kj} = 0 \quad \forall j \in M$$

$$\sum_{k=1}^K Y_{kj} = 1 \quad \forall j \in M$$

- This model is available at <http://www-unix.mcs.anl.gov/~leyffer/macminlp/problems/batch.mod>

## MIQP: Modeling Tricks

- In 0-1 quadratic programming, we can always make quadratic forms convex.
- **Key:** If  $y \in \{0, 1\}$ , then  $y = y^2$ , so add a “large enough” constant to the diagonal, and subtract it from the linear term:
- $y \in \{0, 1\}^n$  consider any quadratic

$$\begin{aligned} q(y) &= y^T Q y + g^T y \\ &= y^T W y + c^T y \end{aligned}$$

where  $W = Q + \lambda I$  and  $c = g - \lambda e$  ( $e = (1, \dots, 1)$ )

- If  $\lambda \geq$ (smallest eigenvalue of  $Q$ ), then  $W \succeq 0$ .

## A Small Smattering of Other Applications

- Chemical Engineering Applications:
  - process synthesis (Kocis and Grossmann, 1988)
  - batch plant design (Grossmann and Sargent, 1979)
  - cyclic scheduling (Jain, V. and Grossmann, I.E., 1998)
  - design of distillation columns (Viswanathan and Grossmann, 1993)
  - pump configuration optimization (Westerlund, T., Pettersson, F. and Grossmann, I.E., 1994)
- Forestry/Paper
  - production (Westerlund, T., Isaksson, J. and Harjunkski, I., 1995)
  - trimloss minimization (Harjunkski, I., Westerlund, T., Pörn, R. and Skrifvars, H., 1998)
- Topology Optimization (Sigmund, 2001)

## Classical Solution Methods for MINLP

### Part II

## Classical Solution Methods

1. Classical Branch-and-Bound
2. Outer Approximation, Benders Decomposition et al.
3. Hybrid Methods
  - LP/NLP Based Branch-and-Bound
  - Integrating SQP with Branch-and-Bound

## Branch-and-Bound

Solve relaxed NLP ( $0 \leq y \leq 1$  continuous relaxation)  
... solution value provides lower bound

- Branch on  $y_i$  non-integral
- Solve NLPs & branch until
  1. Node infeasible ... ●
  2. Node integer feasible ... □  
⇒ get upper bound ( $U$ )
  3. Lower bound  $\geq U$  ... ⊗

Search until no unexplored nodes on tree

## Convergence of Branch-and-Bound

All NLP problems solved globally & finite number of NLPs on tree  
⇒ Branch-and-Bound converges  
≈ complete enumeration at worst

## Variable Selection for Branch-and-Bound

Assume  $y_i \in \{0, 1\}$  for simplicity ...  
 $(\hat{x}, \hat{y})$  fractional solution to parent node;  $\hat{f} = f(\hat{x}, \hat{y})$

1. user defined priorities  
... branch on most important variable first
2. maximal fractional branching

$$\max_i \{ \min(1 - \hat{y}_i, \hat{y}_i) \}$$

... find  $\hat{y}_i$  closest to  $\frac{1}{2}$  ⇒ largest change in problem

## Variable Selection for Branch-and-Bound

Assume  $y_i \in \{0, 1\}$  for simplicity ...  
 $(\hat{x}, \hat{y})$  fractional solution to parent node;  $\hat{f} = f(\hat{x}, \hat{y})$

3. pseudo-cost branching  
estimates  $e_i^+$ ,  $e_i^-$  of change in  $f(x, y)$  after branching

$$\max_i \left\{ \min(\hat{f} + e_i^+(1 - \hat{y}_i), \hat{f} + e_i^-\hat{y}_i) \right\}$$

... find  $y_i$ , whose expected change of objective is largest  
... estimate  $e_i^+$ ,  $e_i^-$  by keeping track of

$$e_i^+ = \frac{f_i^+ - \hat{f}}{1 - \hat{y}_i} \quad \text{and} \quad e_i^- = \frac{f_i^- - \hat{f}}{\hat{y}_i}$$

where  $f_i^{+/-}$  solution value after branching

## Variable Selection for Branch-and-Bound

Assume  $y_i \in \{0, 1\}$  for simplicity ...

$(\hat{x}, \hat{y})$  fractional solution to parent node;  $\hat{f} = f(\hat{x}, \hat{y})$

4. **strong branching**: solve *all* NLP child nodes:

$$f_i^{+/-} \leftarrow \begin{cases} \text{minimize}_{x,y} & f(x, y) \\ \text{subject to} & c(x, y) \leq 0 \\ & x \in X, y \in Y, y_i = 1/0 \end{cases}$$

choose branching variable as

$$\max_i \{ \min(f_i^+, f_i^-) \}$$

... find  $y_i$  that changes objective the most

## Variable Selection for Branch-and-Bound

Assume  $y_i \in \{0, 1\}$  for simplicity ...

$(\hat{x}, \hat{y})$  fractional solution to parent node;  $\hat{f} = f(\hat{x}, \hat{y})$

5. **MIQP strong branching**: (Fletcher and Leyffer, 1998)  
parametric solution of QPs ... much cheaper than re-solve

- step of **dual active set method**
- factorization of KKT matrix
- $\simeq$  multiple KKT solves
- generalizes old MILP ideas

## Node Selection for Branch-and-Bound

Which node  $n$  on tree  $\mathcal{T}$  should be solved next?

1. **depth-first search**

select deepest node in tree

- minimizes number of NLP nodes stored
- exploit warm-starts (MILP/MIQP only)

2. **best lower bound**

choose node with least **value of parent node**  $f_{p(n)}$

- minimizes number of NLPs solved

## Node Selection for Branch-and-Bound

Which node  $n$  on tree  $\mathcal{T}$  should be solved next?

3. **best estimate**

choose node leading to best expected integer solution

$$\min_{n \in \mathcal{T}} \left\{ f_{p(n)} + \sum_{i: y_i \text{ fractional}} \min \{ e_i^+ (1 - y_i), e_i^- y_i \} \right\}$$

where

- $f_{p(n)}$  = value of parent node
- $e_i^{+/-}$  = pseudo-costs

summing pseudo-cost estimates for all integers in subtree

## Outer Approximation (Duran and Grossmann, 1986)

**Motivation:** avoid *solving huge number* of NLPs

- Exploit MILP/NLP solvers: decompose **integer/nonlinear** part

**Key idea:** reformulate MINLP as MILP (implicit)

- Solve **alternating sequence** of MILP & NLP

NLP subproblem  $y_j$  fixed:

$$\text{NLP}(y_j) \begin{cases} \text{minimize}_x & f(x, y_j) \\ \text{subject to} & c(x, y_j) \leq 0 \\ & x \in X \end{cases}$$

Main Assumption:  $f, c$  are **convex**

## Outer Approximation (Duran and Grossmann, 1986)

- let  $(x_j, y_j)$  solve  $\text{NLP}(y_j)$
- linearize  $f, c$  about  $(x_j, y_j) =: z_j$
- new objective variable  $\eta \geq f(x, y)$
- $\text{MINLP}(P) \equiv \text{MILP}(M)$

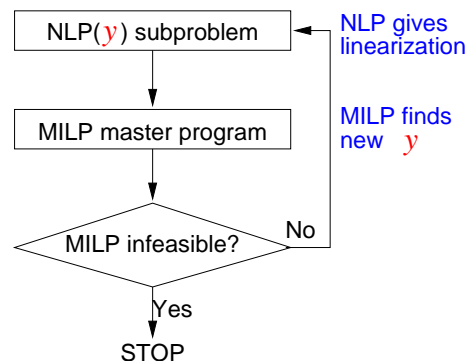

$$(M) \begin{cases} \text{minimize}_{z=(x,y), \eta} & \eta \\ \text{subject to} & \eta \geq f_j + \nabla f_j^T(z - z_j) \quad \forall y_j \in Y \\ & 0 \geq c_j + \nabla c_j^T(z - z_j) \quad \forall y_j \in Y \\ & x \in X, y \in Y \text{ integer} \end{cases}$$

**SNAG:** need *all*  $y_j \in Y$  linearizations

## Outer Approximation (Duran and Grossmann, 1986)

$(M_k)$ : **lower bound** (underestimate convex  $f, c$ )

$\text{NLP}(y_j)$ : **upper bound**  $U$  (fixed  $y_j$ )

$\Rightarrow$  stop, if **lower bound**  $\geq$  **upper bound**

## Convergence of Outer Approximation

**Lemma:** Each  $y_i \in Y$  generated at most once.

**Proof:** Assume  $y_i \in Y$  generated again at iteration  $j > i$   
 $\Rightarrow \exists \hat{x}$  such that  $(\hat{x}, y_i)$  feasible in  $(M_j)$ :

$$\begin{aligned} \eta &\geq f_i + \nabla_x f_i^T(\hat{x} - x_i) \\ 0 &\geq c_i + \nabla_x c_i^T(\hat{x} - x_i) \end{aligned}$$

... because  $y_i - y_i = 0$

Now sum with  $(1, \lambda_i)$  **optimal multipliers of  $\text{NLP}(y_i)$**

$$\Rightarrow \eta \geq f_i + \lambda_i^T c_i + (\nabla_x f_i + \nabla_x c_i \lambda_i)^T(\hat{x} - x_i)$$

... KKT conditions:  $\nabla_x f_i + \nabla_x c_i \lambda_i = 0$  &  $\lambda_i^T c_i = 0$

$\Rightarrow \eta \geq f_i$  contradicts  $\eta < U \leq f_i$  upper bound

$\Rightarrow$  each  $y_i \in Y$  generated at most once □

**Refs:** (Duran and Grossmann, 1986; Fletcher and Leyffer, 1994)

## Convergence of Outer Approximation

1. each  $y_i \in Y$  generated at most once  
&  $|Y| < \infty \Rightarrow$  **finite termination**
2. convexity  $\Rightarrow$  **outer approximation**

$\Rightarrow$  convergence to global min

**Convexity important!!!**

## Outer Approximation & Benders Decomposition

Take OA master ...  $z := (x, y)$  ... wlog  $X = \mathbb{R}^n$

$$(M) \begin{cases} \text{minimize} & \eta \\ z=(x,y),\eta & \\ \text{subject to} & \eta \geq f_j + \nabla f_j^T(z - z_j) \quad \forall y_j \in Y \\ & 0 \geq c_j + \nabla c_j^T(z - z_j) \quad \forall y_j \in Y \\ & y \in Y \text{ integer} \end{cases}$$

$\forall j$  : sum  $0 \geq c_j \dots$  weighted with multipliers  $\lambda_j$  of NLP( $y_j$ )

$$\Rightarrow \eta \geq f_j + \lambda_j^T c_j + (\nabla f_j + \nabla c_j \lambda_j)^T (z - z_j) \quad \forall y_j \in Y$$

... is a valid inequality.

**References:** (Geoffrion, 1972)

## Outer Approximation & Benders Decomposition

Valid inequality from OA master;  $z = (x, y)$ :

$$\eta \geq f_j + \lambda_j^T c_j + (\nabla f_j + \nabla c_j \lambda_j)^T (z - z_j)$$

use **first order conditions** of NLP( $y_j$ ) ...

$$\nabla_x f_j + \nabla_x c_j \lambda_j = 0 \quad \& \quad \lambda_j^T c_j = 0$$

... to **eliminate  $x$  components** from valid inequality **in  $y$**

$$\begin{aligned} \Rightarrow \eta &\geq f_j + (\nabla_y f_j + \nabla_y c_j \lambda_j)^T (y - y_j) \\ \Leftrightarrow \eta &\geq f_j + (\mu_j)^T (y - y_j) \end{aligned}$$

where  $\mu_j = \nabla_y f_j + \nabla_y c_j \lambda_j$  multiplier of  $y = y_j$  in NLP( $y_j$ )

## Outer Approximation & Benders Decomposition

$\Rightarrow$  remove  $x$  from master problem ... **Benders master problem**

$$(M_B) \begin{cases} \text{minimize} & \eta \\ y,\eta & \\ \text{subject to} & \eta \geq f_j + (\mu_j)^T (y - y_j) \quad \forall y_j \in Y \\ & y \in Y \text{ integer} \end{cases}$$

where  $\mu_j$  multiplier of  $y = y_j$  in NLP( $y_j$ )

- ( $M_B$ ) has **less constraints & variables** (no  $x$ !)
- ( $M_B$ ) **almost ILP** (except for  $\eta$ )
- ( $M_B$ ) **weaker** than OA (from derivation)

## Extended Cutting Plane Method

Replace  $NLP(y_i)$  solve in OA by linearization about solution of  $(M_j)$   
 get cutting plane for violated constraint  
 $\Rightarrow$  no  $NLP(y_j)$  solves ...  
 ... Kelley's cutting plane method instead  
 $\Rightarrow$  **slow nonlinear convergence**:  
 $> 1$  evaluation per  $y$

References: (Westerlund, T. and Pettersson, F., 1995)

## Disadvantages of Outer Approximation

- MILP tree-search can be bottle-neck
- potentially large number of iterations

$$\begin{aligned} &\text{minimize} && (y - \frac{1}{2^n})^2 \\ &\text{subject to} && y \in \{0, \frac{1}{2^n}, \dots, 1\} \end{aligned}$$

**Second order master (MIQP)**: (Fletcher and Leyffer, 1994):

- add Hessian term to MILP  $(M_i)$  becomes MIQP:

$$\text{minimize} \quad \eta + \frac{1}{2}(z - z_i)^T W (z - z_i) \quad \text{subject to} \dots$$

## LP/NLP Based Branch-and-Bound

**AIM**: avoid re-solving MILP master  $(M)$

- Consider MILP branch-and-bound
- interrupt MILP, when  $y_j$  found  
 $\Rightarrow$  solve  $NLP(y_j)$  get  $x_j$
- linearize  $f, c$  about  $(x_j, y_j)$   
 $\Rightarrow$  add linearization to tree
- continue MILP tree-search

... until lower bound  $\geq$  upper bound

## LP/NLP Based Branch-and-Bound

- need access to MILP solver ... call back
  - exploit good MILP (branch-cut-price) solver
  - (Akrotirianakis et al., 2001) use Gomory cuts in tree-search
- no commercial implementation of this idea
- preliminary results: order of magnitude faster than OA
  - same number of NLPs, but only one MILP
- similar ideas for Benders & Extended Cutting Plane methods

References: (Quesada and Grossmann, 1992)

## Integrating SQP & Branch-and-Bound

**AIM:** Avoid solving NLP node to convergence.

Sequential Quadratic Programming (SQP)

→ solve sequence  $(QP_k)$  at every node

$$(QP_k) \begin{cases} \text{minimize}_d & f_k + \nabla f_k^T d + \frac{1}{2} d^T H_k d \\ \text{subject to} & c_k + \nabla c_k^T d \leq 0 \\ & x_k + d_x \in X \\ & y_k + d_y \in \hat{Y}. \end{cases}$$

**Early branching:**

After QP step choose non-integral  $y_i^{k+1}$ , branch & continue SQP

**References:** (Borchers and Mitchell, 1994; Leyffer, 2001)

## Integrating SQP & Branch-and-Bound

**SNAG:**  $(QP_k)$  not lower bound

⇒ no fathoming from upper bound

$$\begin{aligned} \text{minimize}_d & f_k + \nabla f_k^T d + \frac{1}{2} d^T H_k d \\ \text{subject to} & c_k + \nabla c_k^T d \leq 0 \\ & x_k + d_x \in X \\ & y_k + d_y \in \hat{Y}. \end{aligned}$$

**Remedy:** Exploit OA underestimating property (Leyffer, 2001):

- add objective cut  $f_k + \nabla f_k^T d \leq U - \epsilon$  to  $(QP_k)$
- fathom node, if  $(QP_k)$  inconsistent  
⇒ converge for convex MINLP

NB:  $(QP_k)$  inconsistent and trust-region active ⇒ do not fathom

## Comparison of Classical MINLP Techniques

**Summary of numerical experience**

1. Quadratic OA master: usually fewer iteration  
MIQP harder to solve
2. NLP branch-and-bound faster than OA  
... depends on MIP solver
3. LP/NLP-based-BB order of magnitude faster than OA  
... also faster than B&B
4. Integrated SQP-B&B up to 3× faster than B&B  
≈ number of QPs per node
5. ECP works well, if function/gradient evals expensive

Part III

Modern Developments in MINLP

## Modern Methods for MINLP

1. Formulations
  - Relaxations
  - Good formulations: big  $M$ 's and disaggregation
2. Cutting Planes
  - Cuts from relaxations and special structures
  - Cuts from integrality
3. Handling Nonconvexity
  - Envelopes
  - Methods

## Relaxations

- $z(S) \stackrel{\text{def}}{=} \min_{x \in S} f(x)$
- $z(T) \stackrel{\text{def}}{=} \min_{x \in T} f(x)$

- Independent of  $f, S, T$ :  
 $z(T) \leq z(S)$
- If  $x_T^* = \arg \min_{x \in T} f(x)$
- And  $x_T^* \in S$ , then
- $x_T^* = \arg \min_{x \in S} f(x)$

## A Pure Integer Program

$$z(S) = \min\{c^T x : x \in S\}, \quad S = \{x \in \mathbb{Z}_+^n : Ax \leq b\}$$

$$\begin{aligned} S &= \{(x_1, x_2) \in \mathbb{Z}_+^2 : 6x_1 + x_2 \leq 15, \\ &\quad 5x_1 + 8x_2 \leq 20, x_2 \leq 2\} \\ &= \{(0, 0), (0, 1), (0, 2), (1, 0), \\ &\quad (1, 1), (1, 2), (2, 0)\} \end{aligned}$$

## How to Solve Integer Programs?

- Relaxations!
  - $T \supseteq S \Rightarrow z(T) \leq z(S)$
  - People commonly use the linear programming relaxation:

$$\begin{aligned} z(LP(S)) &= \min\{c^T x : x \in LP(S)\} \\ LP(S) &= \{x \in \mathbb{R}_+^n : Ax \leq b\} \end{aligned}$$

- If  $LP(S) = \text{conv}(S)$ , we are done.
- Minimum of **any** linear function over **any** convex set occurs on the boundary
- We need only know  $\text{conv}(S)$  in the direction of  $c$ .
- The “closer”  $LP(S)$  is to  $\text{conv}(S)$  the better.

# Small M's Good. Big M's Baaaaaaaaaaaaaaaaaad!

$P$

- Sometimes, we can get a better relaxation (make  $LP(S)$  a closer approximation to  $conv(S)$ ) through a different tighter formulation
- Let's look at the geometry

$$P = \{x \in \mathbb{R}_+, z \in \{0, 1\} : x \leq Mz, x \leq u\}$$

$$LP(P) = \{x \in \mathbb{R}_+, z \in [0, 1] : x \leq Mz, x \leq u\}$$

$$conv(P) = \{x \in \mathbb{R}_+, z \in \{0, 1\} : x \leq uz\}$$

$$P = \{x \in \mathbb{R}_+, z \in \{0, 1\} : x \leq Mz, x \leq u\}$$

## LP Versus Conv

$$LP(P) = \{x \in \mathbb{R}_+, z \in [0, 1] : x \leq Mz, x \leq u\}$$

$$conv(P) = \{x \in \mathbb{R}_+, z \in [0, 1] : x \leq uz\}$$

- **KEY:** If  $M = u$ ,  $LP(P) = conv(P)$
- **Small M's good. Big M's baaaaaaaaaad.**

## UFL: Uncapacitated Facility Location

- Facilities:  $I$
- Customers:  $J$

$$\min \sum_{j \in J} f_j x_j + \sum_{i \in I} \sum_{j \in J} f_{ij} y_{ij}$$

$$\sum_{j \in J} y_{ij} = 1 \quad \forall i \in I$$

$$\sum_{i \in I} y_{ij} \leq |I| x_j \quad \forall j \in J \quad (1)$$

$$\text{OR } y_{ij} \leq x_j \quad \forall i \in I, j \in J \quad (2)$$

- Which formulation is to be preferred?
- $I = J = 40$ . Costs random.
  - Formulation 1. 53,121 seconds, optimal solution.
  - Formulation 2. 2 seconds, optimal solution.

## Valid Inequalities

- Sometimes we can get a better formulation by **dynamically** improving it.

- An inequality  $\pi^T x \leq \pi_0$  is a **valid inequality** for  $S$  if  $\pi^T x \leq \pi_0 \forall x \in S$
- Alternatively:  $\max_{x \in S} \{\pi^T x\} \leq \pi_0$

- Thm:** (Hahn-Banach). Let  $S \subset \mathbb{R}^n$  be a closed, convex set, and let  $\hat{x} \notin S$ . Then there exists  $\pi \in \mathbb{R}^n$  such that

$$\pi^T \hat{x} > \max_{x \in S} \{\pi^T x\}$$

## Nonlinear Branch-and-Cut

Consider MINLP

$$\begin{cases} \text{minimize}_{x,y} & f_x^T x + f_y^T y \\ \text{subject to} & c(x,y) \leq 0 \\ & y \in \{0,1\}^p, 0 \leq x \leq U \end{cases}$$

- Note the **Linear objective**
- This is WLOG:

$$\min f(x,y) \Leftrightarrow \min \eta \text{ s.t. } \eta \geq f(x,y)$$

## It's Actually Important!

- We want to approximate the convex hull of integer solutions, but without a linear objective function, the solution to the relaxation might occur in the interior.
- No Separating Hyperplane!** :- (

$$\min (y_1 - 1/2)^2 + (y_2 - 1/2)^2$$

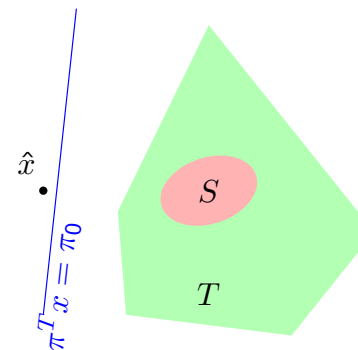

$$\text{s.t. } y_1 \in \{0,1\}, y_2 \in \{0,1\}$$

$$\eta \geq (y_1 - 1/2)^2 + (y_2 - 1/2)^2$$

## Valid Inequalities From Relaxations

- Idea:** Inequalities valid for a relaxation are valid for original
- Generating valid inequalities for a relaxation is often easier.

- Separation Problem** over  $T$ : Given  $\hat{x}, T$  find  $(\pi, \pi_0)$  such that  $\pi^T \hat{x} > \pi_0$ ,  $\pi^T x \leq \pi_0 \forall x \in T$

## Simple Relaxations

- **Idea:** Consider **one row** relaxations ☀
- If  $P = \{x \in \{0, 1\}^n \mid Ax \leq b\}$ , then for any row  $i$ ,  $P_i = \{x \in \{0, 1\}^n \mid a_i^T x \leq b_i\}$  is a relaxation of  $P$ .
- If the intersection of the relaxations is a good approximation to the true problem, then the inequalities will be quite useful.
- Crowder et al. (1983) is the seminal paper that shows this to be true for IP.
- **MINLP:** Single (linear) row relaxations are also valid  $\Rightarrow$  **same inequalities can also be used**

## Knapsack Covers

$$K = \{x \in \{0, 1\}^n \mid a^T x \leq b\}$$

- A set  $C \subseteq N$  is a **cover** if  $\sum_{j \in C} a_j > b$
- A cover  $C$  is a **minimal cover** if  $C \setminus j$  is not a cover  $\forall j \in C$
- If  $C \subseteq N$  is a cover, then the *cover inequality*

$$\sum_{j \in C} x_j \leq |C| - 1$$

is a valid inequality for  $S$

- Sometimes (minimal) cover inequalities are **facets** of  $\text{conv}(K)$

## Example

$$K = \{x \in \{0, 1\}^7 \mid 11x_1 + 6x_2 + 6x_3 + 5x_4 + 5x_5 + 4x_6 + x_7 \leq 19\}$$

$$LP(K) = \{x \in [0, 1]^7 \mid 11x_1 + 6x_2 + 6x_3 + 5x_4 + 5x_5 + 4x_6 + x_7 \leq 19\}$$

- $(1, 1, 1/3, 0, 0, 0, 0) \in LP(K)$ 
  - **CHOPPED OFF BY**  $x_1 + x_2 + x_3 \leq 2$
- $(0, 0, 1, 1, 1, 3/4, 0) \in LP(K)$ 
  - **CHOPPED OFF BY**  $x_3 + x_4 + x_5 + x_6 \leq 3$

## Other Substructures

- **Single node flow:** (Padberg et al., 1985)

$$S = \left\{ x \in \mathbb{R}_+^{|N|}, y \in \{0, 1\}^{|N|} \mid \sum_{j \in N} x_j \leq b, x_j \leq u_j y_j \quad \forall j \in N \right\}$$

- **Knapsack with single continuous variable:** (Marchand and Wolsey, 1999)

$$S = \left\{ x \in \mathbb{R}_+, y \in \{0, 1\}^{|N|} \mid \sum_{j \in N} a_j y_j \leq b + x \right\}$$

- **Set Packing:** (Borndörfer and Weismantel, 2000)

$$S = \{y \in \{0, 1\}^{|N|} \mid Ay \leq e\}$$

$$A \in \{0, 1\}^{|M| \times |N|}, e = (1, 1, \dots, 1)^T$$

## The Chvátal-Gomory Procedure

- A **general** procedure for generating valid inequalities for integer programs
- Let the columns of  $A \in \mathbb{R}^{m \times n}$  be denoted by  $\{a_1, a_2, \dots, a_n\}$
- $S = \{y \in \mathbb{Z}_+^n \mid Ay \leq b\}$ .
  1. Choose nonnegative multipliers  $u \in \mathbb{R}_+^m$
  2.  $u^T Ay \leq u^T b$  is a valid inequality ( $\sum_{j \in N} u^T a_j y_j \leq u^T b$ ).
  3.  $\sum_{j \in N} \lfloor u^T a_j \rfloor y_j \leq u^T b$  (Since  $y \geq 0$ ).
  4.  $\sum_{j \in N} \lfloor u^T a_j \rfloor y_j \leq \lfloor u^T b \rfloor$  is valid for  $S$  since  $\lfloor u^T a_j \rfloor y_j$  is an integer
- **Simply Amazing**: This simple procedure **suffices** to generate every valid inequality for an integer program

## Extension to MINLP (Çezik and Iyengar, 2005)

- This simple idea also extends to mixed 0-1 **conic** programming

$$\begin{cases} \text{minimize} & f^T z \\ & z \stackrel{\text{def}}{=} (x, y) \\ \text{subject to} & Az \succeq_{\mathcal{K}} b \\ & y \in \{0, 1\}^p, 0 \leq x \leq U \end{cases}$$

- $\mathcal{K}$ : Homogeneous, self-dual, proper, convex cone
- $x \succeq_{\mathcal{K}} y \Leftrightarrow (x - y) \in \mathcal{K}$

## Gomory On Cones (Çezik and Iyengar, 2005)

- **LP**:  $\mathcal{K}_l = \mathbb{R}_+^n$
- **SOCP**:  $\mathcal{K}_q = \{(x_0, \bar{x}) \mid x_0 \geq \|\bar{x}\|\}$
- **SDP**:  $\mathcal{K}_s = \{x = \text{vec}(X) \mid X = X^T, X \text{ p.s.d}\}$
- **Dual Cone**:  $\mathcal{K}^* \stackrel{\text{def}}{=} \{u \mid u^T z \geq 0 \forall z \in \mathcal{K}\}$
- Extension is clear from the following equivalence:

$$Az \succeq_{\mathcal{K}} b \Leftrightarrow u^T Az \geq u^T b \forall u \succeq_{\mathcal{K}^*} 0$$

- Many classes of nonlinear inequalities can be represented as
  - **Go to other SIAM Short Course to find out about Semidefinite Programming**

$$Ax \succeq_{\mathcal{K}_q} b \text{ or } Ax \succeq_{\mathcal{K}_s} b$$

## Mixed Integer Rounding—MIR

Almost **everything** comes from considering the following very simple set, and observation.

- $X = \{(x, y) \in \mathbb{R} \times \mathbb{Z} \mid y \leq b + x\}$
- $f = b - \lfloor b \rfloor$ : **fractional**
  - **NLP People are silly** and use  $f$  for the objective function
- $LP(X)$
- $\text{conv}(X)$
- $y \leq \lfloor b \rfloor + \frac{1}{1-f}x$  is a valid inequality for  $X$

## Extension of MIR

$$X_2 = \left\{ (x^+, x^-, y) \in \mathbb{R}_+^2 \times \mathbb{Z}^{|N|} \mid \sum_{j \in N} a_j y_j + x^+ \leq b + x^- \right\}$$

- The inequality

$$\sum_{j \in N} \left( \lfloor a_j \rfloor + \frac{(f_j - f)^+}{1 - f} \right) y_j \leq \lfloor b \rfloor + \frac{x^-}{1 - f}$$

is valid for  $X_2$

- $f_j \stackrel{\text{def}}{=} a_j - \lfloor a_j \rfloor$ ,  $(t)^+ \stackrel{\text{def}}{=} \max(t, 0)$
- $X_2$  is a one-row relaxation of a general *mixed* integer program
  - Continuous variables aggregated into two:  $x^+, x^-$

## It's So Easy, Even I Can Do It

**Proof:**

- $N_1 = \{j \in N \mid f_j \leq f\}$
- $N_2 = N \setminus N_1$
- Let

$$P = \left\{ (x, y) \in \mathbb{R}_+^2 \times \mathbb{Z}^{|N|} \mid \sum_{j \in N_1} \lfloor a_j \rfloor y_j + \sum_{j \in N_2} \lceil a_j \rceil y_j \leq b + x^- + \sum_{j \in N_2} (1 - f_j) y_j \right\}$$

- Show  $X_2 \subseteq P$
- Show simple (2-variable) MIR inequality is valid for  $P$  (with an appropriate variable substitution).
- Collect the terms

## Gomory Mixed Integer Cut is a MIR Inequality

- Consider the set

$$X^= = \left\{ (x^+, x^-, y_0, y) \in \mathbb{R}_+^2 \times \mathbb{Z} \times \mathbb{Z}_+^{|N|} \mid y_0 + \sum_{j \in N} a_j y_j + x^+ - x^- = b \right\}$$

which is essentially the row of an LP tableau

- Relax the equality to an inequality and apply MIR
- Gomory Mixed Integer Cut:**

$$\sum_{j \in N_1} f_j y_j + x^+ + \frac{f}{1 - f} x^- + \sum_{j \in N_2} \left( f_j - \frac{f_j - f}{1 - f} \right) y_j \geq f$$

## Using Gomory Cuts in MINLP (Akrotirianakis et al., 2001)

- LP/NLP Based Branch-and-Bound solves MILP instances:

$$\begin{cases} \text{minimize} & \eta \\ z \stackrel{\text{def}}{=} (x, y), \eta & \\ \text{subject to} & \eta \geq f_j + \nabla f_j^T (z - z_j) \quad \forall y_j \in Y^k \\ & 0 \geq c_j + \nabla c_j^T (z - z_j) \quad \forall y_j \in Y^k \\ & x \in X, y \in Y \text{ integer} \end{cases}$$

- Create Gomory mixed integer cuts from

$$\begin{aligned} \eta &\geq f_j + \nabla f_j^T (z - z_j) \\ 0 &\geq c_j + \nabla c_j^T (z - z_j) \end{aligned}$$

- Akrotirianakis et al. (2001) shows modest improvements
- Research Question:** Other cut classes?
- Research Question:** Exploit “outer approximation” property?

## Disjunctive Cuts for MINLP (Stubbs and Mehrotra, 1999)

Extension of Disjunctive Cuts for MILP: (Balas, 1979; Balas et al., 1993)

Continuous relaxation ( $z \stackrel{\text{def}}{=} (x, y)$ )

- $C \stackrel{\text{def}}{=} \{z | c(z) \leq 0, 0 \leq y \leq 1, 0 \leq x \leq U\}$
- $C \stackrel{\text{def}}{=} \text{conv}(\{x \in C | y \in \{0, 1\}^p\})$
- $C_j^{0/1} \stackrel{\text{def}}{=} \{z \in C | y_j = 0/1\}$

$$\text{let } \mathcal{M}_j(C) \stackrel{\text{def}}{=} \left\{ \begin{array}{l} z = \lambda_0 u_0 + \lambda_1 u_1 \\ \lambda_0 + \lambda_1 = 1, \lambda_0, \lambda_1 \geq 0 \\ u_0 \in C_j^0, u_1 \in C_j^1 \end{array} \right\}$$

$\Rightarrow \mathcal{P}_j(C) := \text{projection of } \mathcal{M}_j(C) \text{ onto } z$

$\Rightarrow \mathcal{P}_j(C) = \text{conv}(C \cap y_j \in \{0, 1\})$  and  $\mathcal{P}_{1\dots p}(C) = C$

## Disjunctive Cuts: Example

$$\text{minimize}_{x,y} \{x \mid (x - 1/2)^2 + (y - 3/4)^2 \leq 1, -2 \leq x \leq 2, y \in \{0, 1\}\}$$

Given  $\hat{z}$  with  $\hat{y}_j \notin \{0, 1\}$  find separating hyperplane

$$\Rightarrow \begin{cases} \text{minimize}_z & \|z - \hat{z}\| \\ \text{subject to} & z \in \mathcal{P}_j(C) \end{cases}$$

## Disjunctive Cuts Example

$$z^* \stackrel{\text{def}}{=} \arg \min \|z - \hat{z}\|$$

$$\text{s.t. } \begin{array}{l} \lambda_0 u_0 + \lambda_1 u_1 = z \\ \lambda_0 + \lambda_1 = 1 \\ \begin{pmatrix} -0.16 \\ 0 \end{pmatrix} \leq u_0 \leq \begin{pmatrix} 0.66 \\ 1 \end{pmatrix} \\ \begin{pmatrix} -0.47 \\ 0 \end{pmatrix} \leq u_1 \leq \begin{pmatrix} 1.47 \\ 1 \end{pmatrix} \\ \lambda_0, \lambda_1 \geq 0 \end{array}$$

NONCONVEX

## What to do? (Stubbs and Mehrotra, 1999)

- Look at the **perspective** of  $c(z)$

$$\mathcal{P}(c(\tilde{z}), \mu) = \mu c(\tilde{z}/\mu)$$

- Think of  $\tilde{z} = \mu z$
- Perspective gives a **convex reformulation** of  $\mathcal{M}_j(C)$ :  $\mathcal{M}_j(\tilde{C})$ , where

$$\tilde{C} := \left\{ (z, \mu) \mid \begin{array}{l} \mu c_i(z/\mu) \leq 0 \\ 0 \leq \mu \leq 1 \\ 0 \leq x \leq \mu U, 0 \leq y \leq \mu \end{array} \right\}$$

- $c(0/0) = 0 \Rightarrow \text{convex representation}$

## Disjunctive Cuts Example

## Example, cont.

$$\tilde{C}_j^0 = \{(z, \mu) \mid y_j = 0\} \quad \tilde{C}_j^1 = \{(z, \mu) \mid y_j = \mu\}$$

- Take  $v_0 \leftarrow \mu_0 u_0$   $v_1 \leftarrow \mu_1 u_1$   
 $\min \|z - \hat{z}\|$

Solution to example:

$$\begin{aligned} \text{s.t. } v_0 + v_1 &= z \\ \mu_0 + \mu_1 &= 1 \\ (v_0, \mu_0) &\in \tilde{C}_j^0 \\ (v_1, \mu_1) &\in \tilde{C}_j^1 \\ \mu_0, \mu_1 &\geq 0 \end{aligned} \quad \begin{pmatrix} x^* \\ y^* \end{pmatrix} = \begin{pmatrix} -0.401 \\ 0.780 \end{pmatrix}$$

- separating hyperplane:  $\psi^T(z - \hat{z})$ , where  $\psi \in \partial \|z - \hat{z}\|$

## Example, Cont.

$$\psi = \begin{pmatrix} 2x^* + 0.5 \\ 2y^* - 0.75 \end{pmatrix}$$

$$0.198x + 0.061y \geq -0.032$$

## Nonlinear Branch-and-Cut (Stubbs and Mehrotra, 1999)

- Can do this at *all* nodes of the branch-and-bound tree
- Generalize disjunctive approach from MILP
  - solve **one convex NLP per cut**
- Generalizes Sherali and Adams (1990) and Lovász and Schrijver (1991)
  - tighten cuts by adding semi-definite constraint
- Stubbs and Mehrotra (2002) also show how to generate convex quadratic inequalities, but computational results are not that promising

## Generalized Disjunctive Programming (Raman and Grossmann, 1994; Lee and Grossmann, 2000)

Consider **disjunctive NLP**

$$\begin{cases} \text{minimize}_{x,Y} & \sum f_i + f(x) \\ \text{subject to} & \begin{bmatrix} Y_i \\ c_i(x) \leq 0 \\ f_i = \gamma_i \end{bmatrix} \vee \begin{bmatrix} -Y_i \\ B_i x = 0 \\ f_i = 0 \end{bmatrix} \forall i \in I \\ & 0 \leq x \leq U, \Omega(Y) = \text{true}, Y \in \{\text{true}, \text{false}\}^p \end{cases}$$

convex hull representation ...

$$\begin{aligned} x &= v_{i1} + v_{i0}, & \lambda_{i1} + \lambda_{i0} &= 1 \\ \lambda_{i1} c_i(v_{i1}/\lambda_{i1}) &\leq 0, & B_i v_{i0} &= 0 \\ 0 \leq v_{ij} &\leq \lambda_{ij} U, & 0 \leq \lambda_{ij} &\leq 1, & f_i &= \lambda_{i1} \gamma_i \end{aligned}$$

## Disjunctive Programming: Example

## Dealing with Nonconvexities

- Functional nonconvexity causes serious problems.
  - Branch and bound must have **true** lower bound (global solution)
- Underestimate nonconvex functions. Solve relaxation. Provides lower bound.
- If relaxation is not exact, then branch

## Dealing with Nonconvex Constraints

- If nonconvexity in constraints, may need to overestimate and underestimate the function to get a convex region

## Envelopes

$$f : \Omega \rightarrow \mathbb{R}$$

- **Convex Envelope** ( $\text{vex}_{\Omega}(f)$ ): Pointwise supremum of convex underestimators of  $f$  over  $\Omega$ .
- **Concave Envelope** ( $\text{cav}_{\Omega}(f)$ ): Pointwise infimum of concave overestimators of  $f$  over  $\Omega$ .

## Branch-and-Bound Global Optimization Methods

- Under/Overestimate “simple” parts of (Factorable) Functions individually
  - Bilinear Terms
  - Trilinear Terms
  - Fractional Terms
  - Univariate convex/concave terms
- General nonconvex functions  $f(x)$  can be underestimated over a region  $[l, u]$  “overpowering” the function with a quadratic function that is  $\leq 0$  on the region of interest

$$\mathcal{L}(x) = f(x) + \sum_{i=1}^n \alpha_i (l_i - x_i)(u_i - x_i)$$

Refs: (McCormick, 1976; Adjiman et al., 1998; Tawarmalani and Sahinidis, 2002)

## Bilinear Terms

The convex and concave envelopes of the bilinear function  $xy$  over a rectangular region

$$R \stackrel{\text{def}}{=} \{(x, y) \in \mathbb{R}^2 \mid l_x \leq x \leq u_x, l_y \leq y \leq u_y\}$$

are given by the expressions

$$\begin{aligned} \text{vex}_{xy_R}(x, y) &= \max\{l_y x + l_x y - l_x l_y, u_y x + u_x y - u_x u_y\} \\ \text{cav}_{xy_R}(x, y) &= \min\{u_y x + l_x y - l_x u_y, l_y x + u_x y - u_x l_y\} \end{aligned}$$

## Worth 1000 Words?

## Disaggregation Tawarmalani et al. (2002)

Consider convex problem with bilinear objective

$$\begin{cases} \text{minimize} & w \sum_{i=1}^n c_i x_i \\ \text{subject to} & (w, x) \in P \quad \text{Polyhedron} \\ & 0 \leq w \leq v \quad 0 \leq x \leq u \end{cases}$$

### Formulation #1

$$\begin{aligned} & \min z \\ & \text{s.t. } (w, x) \in P \\ & \quad 0 \leq z \\ & \left( \sum_{i=1}^n c_i u_i \right) w + v \left( \sum_{i=1}^n c_i x_i \right) \\ & \quad -v \left( \sum_{i=1}^n c_i u_i \right) \leq 0 \end{aligned}$$

### Formulation #2

$$\begin{aligned} & \min \sum_{i=1}^n z_i \\ & \text{s.t. } (w, x) \in P \\ & \quad 0 \leq z_i \quad \forall i \\ & \quad c_i u_i w + v c_i x_i \\ & \quad -v c_i u_i \leq 0 \quad \forall i \end{aligned}$$

MINLP

Leyffer & Linderoth  
Special Ordered Sets  
Parallel BB and Grid Computing  
Implementation & Software Issues

MINLP

## Summary

- MINLP: **Good** relaxations are important
- Relaxations can be improved
  - **Statically**: Better formulation/preprocessing
  - **Dynamically**: Cutting planes
- Nonconvex MINLP:
  - Methods exist, again based on relaxations
- Tight relaxations is an active area of research
- **Lots** of empirical questions remain

## Implementation and Software for MINLP

### Part IV

### Implementation and Software

1. Special Ordered Sets
2. Parallel BB and Grid Computing
3. Implementation & Software Issues

## Special Ordered Sets of Type 1

SOS1:  $\sum \lambda_i = 1$  & at most one  $\lambda_i$  is nonzero

**Example 1:**  $d \in \{d_1, \dots, d_p\}$  discrete diameters

$\Leftrightarrow d = \sum \lambda_i d_i$  and  $\{\lambda_1, \dots, \lambda_p\}$  is SOS1

$\Leftrightarrow d = \sum \lambda_i d_i$  and  $\sum \lambda_i = 1$  and  $\lambda_i \in \{0, 1\}$

...  $d$  is convex combination with coefficients  $\lambda_i$

**Example 2:** nonlinear function  $c(y)$  of single integer

$\Leftrightarrow y = \sum i \lambda_i$  and  $c = \sum c(i) \lambda_i$  and  $\{\lambda_1, \dots, \lambda_p\}$  is SOS1

**References:** (Beale, 1979; Nemhauser, G.L. and Wolsey, L.A., 1988; Williams, 1993) ...

## Special Ordered Sets of Type 1

SOS1:  $\sum \lambda_i = 1$  & at most one  $\lambda_i$  is nonzero

### Branching on SOS1

- reference row  $a_1 < \dots < a_p$   
e.g. diameters
- fractionality:  $a := \sum a_i \lambda_i$
- find  $t : a_t < a \leq a_{t+1}$
- branch:  $\{\lambda_{t+1}, \dots, \lambda_p\} = 0$   
or  $\{\lambda_1, \dots, \lambda_t\} = 0$

## Special Ordered Sets of Type 2

SOS2:  $\sum \lambda_i = 1$  & at most two adjacent  $\lambda_i$  nonzero

**Example:** Approximation of nonlinear function  $z = z(x)$

- breakpoints  $x_1 < \dots < x_p$
- function values  $z_i = z(x_i)$
- piece-wise linear
- $x = \sum \lambda_i x_i$
- $z = \sum \lambda_i z_i$
- $\{\lambda_1, \dots, \lambda_p\}$  is SOS2

... convex combination of two breakpoints ...

## Special Ordered Sets of Type 2

SOS2:  $\sum \lambda_i = 1$  & at most two adjacent  $\lambda_i$  nonzero

### Branching on SOS2

- reference row  $a_1 < \dots < a_p$   
e.g.  $a_i = x_i$
- fractionality:  $a := \sum a_i \lambda_i$
- find  $t : a_t < a \leq a_{t+1}$
- branch:  $\{\lambda_{t+1}, \dots, \lambda_p\} = 0$   
or  $\{\lambda_1, \dots, \lambda_{t-1}\} = 0$

## Special Ordered Sets of Type 3

**Example:** Approximation of 2D function  $u = g(v, w)$

Triangularization of  $[v_L, v_U] \times [w_L, w_U]$  domain

1.  $v_L = v_1 < \dots < v_k = v_U$
2.  $w_L = w_1 < \dots < w_l = w_U$
3. function  $u_{ij} := g(v_i, w_j)$
4.  $\lambda_{ij}$  weight of vertex  $(i, j)$

- $v = \sum \lambda_{ij} v_i$
- $w = \sum \lambda_{ij} w_j$
- $u = \sum \lambda_{ij} u_{ij}$

$1 = \sum \lambda_{ij}$  is SOS3 ...

## Special Ordered Sets of Type 3

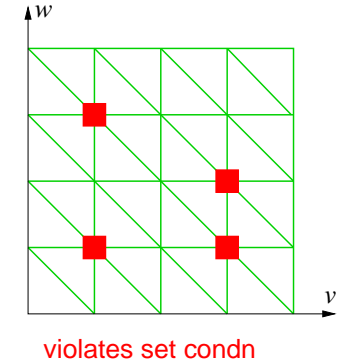

SOS3:  $\sum \lambda_{ij} = 1$  & set condition holds

1.  $v = \sum \lambda_{ij} v_i$  ... convex combinations
2.  $w = \sum \lambda_{ij} w_j$
3.  $u = \sum \lambda_{ij} u_{ij}$

$\{\lambda_{11}, \dots, \lambda_{kl}\}$  satisfies set condition

$\Leftrightarrow \exists$  triangle  $\Delta : \{(i, j) : \lambda_{ij} > 0\} \subset \Delta$

i.e. nonzeros in single triangle  $\Delta$

## Branching on SOS3

$\lambda$  violates set condition

- compute centers:  
 $\hat{v} = \sum \lambda_{ij} v_i$  &  
 $\hat{w} = \sum \lambda_{ij} w_j$
- find  $s, t$  such that  
 $v_s \leq \hat{v} < v_{s+1}$  &  
 $w_s \leq \hat{w} < w_{s+1}$
- branch on  $v$  or  $w$

vertical branching:  $\sum_L \lambda_{ij} = 1$      $\sum_R \lambda_{ij} = 1$     horizontal

branching:  $\sum_T \lambda_{ij} = 1$      $\sum_B \lambda_{ij} = 1$

## Branching on SOS3

**Example:** gas network from first lecture ...

- pressure loss  $p$  across pipe is related to flow rate  $f$  as

$$p_{in}^2 - p_{out}^2 = \Psi^{-1} \text{sign}(f) f^2 \Leftrightarrow p_{in} = \sqrt{p_{out}^2 + \Psi^{-1} \text{sign}(f) f^2}$$

where  $\Psi$ : "Friction Factor"

- nonconvex equation  $u = g(v, w)$   
... assume pressures needed elsewhere
- (Martin et al., 2005) use SOS3 model  
... study polyhedral properties  
... solve medium sized problem

## Parallel Branch-and-Bound

### meta-computing platforms:

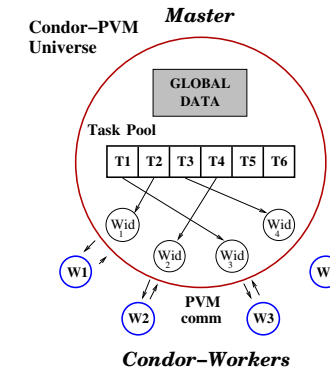

- set of **distributed heterogeneous computers**, e.g.
  - pool of workstations
  - group of supercomputers or anything
- **low quality** with respect to bandwidth, latency, availability
- **low cost: it's free!!!** ... huge amount of resources

... use *Condor* to “build” MetaComputer  
... high-throughput computing

## Parallel Branch-and-Bound

### Master Worker Paradigm (*MWdriver*)

Object oriented C++ library on top of Condor-PVM

*Fault tolerance* via master *check-pointing*

## Parallel Branch-and-Bound

**First Strategy:** 1 worker  $\equiv$  1 NLP  
 $\Rightarrow$  grain-size *too small*  
... NLPs solve in seconds

**New Strategy:**  
1 worker  $\equiv$  1 subtree (MINLP)  
... “streamers” running down tree

**Important:** workers remove “small tasks”  
... before returning tree to master

## Parallel Branch-and-Bound

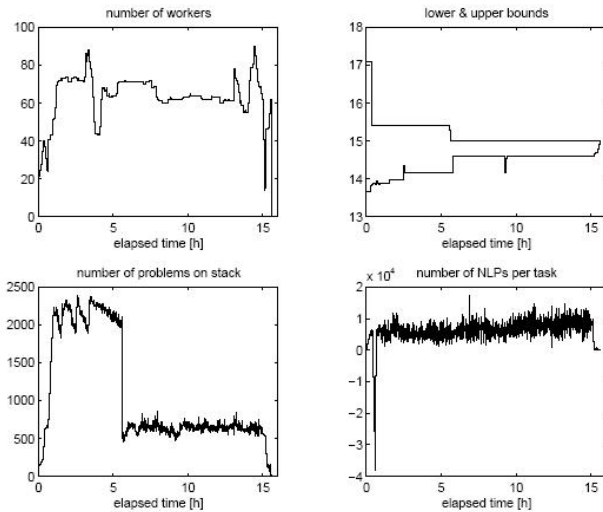

Trimloss optimization with 56 general integers  
 $\Rightarrow$  solve 96,408 MINLPs on 62.7 workers  
 $\Rightarrow$  600,518,018 NLPs

Wall clock time = 15.5 hours  
Cumulative worker CPU time = 752.7 hours  $\simeq$  31 days

$$\text{efficiency} := \frac{\text{work-time}}{\text{work} \times \text{job-time}} = \frac{752.7}{62.7 \times 15.5} = 80.5$$

... **proportion of time workers were busy**

## Parallel Branch-and-Bound: Results

## Detecting Infeasibility

NLP node inconsistent (BB, OA, GBD)  
 $\Rightarrow$  NLP solver **must prove infeasibility**  
 $\Rightarrow$  solve feasibility problem: **restoration**

$$(F) \begin{cases} \text{minimize} & \|c^+(x, y)\| \\ \text{subject to} & x \in X, y \in \hat{Y} \end{cases}$$

where  $c^+(x, y) = \max(c(x, y), 0)$  and  $\| \cdot \|$  any norm

If  $\exists$  solution  $(\hat{x}, \hat{y})$  such that  $\|c^+(\hat{x}, \hat{y})\| > 0$   
 $\Rightarrow$  no feasible point (if **convex**) in neighborhood (if **nonconvex**)

## Feasibility Cuts for OA et al.

$\hat{Y} = \{\hat{y}\}$  singleton &  $c(c, y)$  convex

$(\hat{x}, \hat{y})$  solves  $F(\hat{y})$  with  $\|c^+(\hat{x}, \hat{y})\| > 0$   
 $\Rightarrow$  valid cut to eliminate  $\hat{y}$  given by

$$0 \geq c^+(\hat{x}, \hat{y}) + \hat{\gamma}^T \begin{pmatrix} x - \hat{x} \\ y - \hat{y} \end{pmatrix}$$

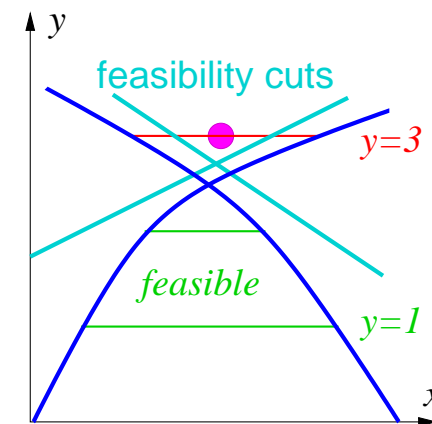

where  $\hat{\gamma} \in \partial \|c^+(\hat{x}, \hat{y})\|$  subdifferential

**Polyhedral norms:**  $\hat{\gamma} = \nabla \hat{c} \lambda$  where

1.  $l_\infty$  norm:  $\sum \lambda_i = 1$ , and  $0 \leq \lambda_i \perp \hat{c}_i \leq \|\hat{c}^+\|$
2.  $l_1$  norm:  $0 \leq \lambda_i \leq 1 \perp -\hat{c}_i$

...  $\lambda$  multipliers of equivalent **smooth NLP** ... easy exercise

## Geometry of Feasibility Cuts

$y = 3$  infeasible  
 solution to feasibility problem  
 feasibility cuts for OA

## Infeasibility in Branch-and-Bound

### FilterSQP restoration phase

- satisfiable constraints:  $J := \{j : c_j(\hat{x}, \hat{y}) \leq 0\}$
- violated constraints  $J^\perp$  (complement of  $J$ )

$$\begin{cases} \text{minimize}_{x,y} & \sum_{j \in J^\perp} c_j(x, y) \\ \text{subject to} & c_j(x, y) \leq 0 \quad \forall j \in J \\ & x \in X, y \in \hat{Y} \end{cases}$$

- filter SQP algorithm on  $\|c_J^+\|$  and  $\|c_{J^\perp}^+\|$   
⇒ 2nd order convergence
- adaptively change  $J$
- similar to  $\ell_1$ -norm, but  $\lambda_i \not\leq 1$

## Choice of NLP Solver

### MILP/MIQP branch-and-bound

- $(\hat{x}, \hat{y})$  solution to parent node
  - new bound:  $y_i \geq \lfloor \hat{y}_i \rfloor$  added to parent LP/QP
- ⇒ dual active set method;  $(\hat{x}, \hat{y})$  dual feasible  
⇒ fast re-optimization (MIQP 2-3 pivots!)

MILP exploit factorization of constraint basis

⇒ no re-factorization, just updates

... also works for MIQP (KKT matrix factorization)

⇒ interior-point methods **not competitive**

... how to check  $\lambda_i > 0$  for SOS branching ???

... how to warm-start IPMs ???

## Choice of NLP Solver

### MINLP branch-and-bound

- $(\hat{x}, \hat{y})$  solution to parent node
- new bound:  $y_i \geq \lfloor \hat{y}_i \rfloor$  added to parent NLP

Snag:  $\nabla c(x, y)$ ,  $\nabla^2 \mathcal{L}$  etc. change ...

- factorized KKT system at  $(x^k, y^k)$  to find step  $(d_x, d_y)$
- NLP solution:  
 $(\hat{x}, \hat{y}) = (x^{k+1}, y^{k+1}) = (x^k + \alpha d_x, y^k + \alpha d_y)$   
but KKT system at  $(x^{k+1}, y^{k+1})$  never factorized

... SQP methods take 2-3 iterations (good active set)

### Outer Approximation et al.

no good warm start ( $y$  changes too much)

⇒ interior-point methods or SQP can be used

## Software for MINLP

- **Outer Approximation:** DICOPT++
- **Branch-and-Bound Solvers:** SBB & MINLP
- **Global MINLP:** BARON & MINOPT
- **Online Tools:** MINLP World, MacMINLP & NEOS

## Outer Approximation: DICOPT++

Outer approximation with equality relaxation & penalty

**Reference:** (Kocis and Grossmann, 1989)

**Features:**

- GAMS interface
- NLP solvers: CONOPT, MINOS, SNOPT
- MILP solvers: CPLEX, OSL2
- solve root NLP, or  $NLP(y^0)$  initially
- **relax linearizations of nonlinear equalities:**  
 $\lambda_i$  multiplier of  $c_i(z) = 0 \dots$

$$c_i(\hat{z}) + \nabla c_i(\hat{z})^T (z - \hat{z}) \begin{cases} \geq 0 & \text{if } \lambda_i > 0 \\ \leq 0 & \text{if } \lambda_i < 0 \end{cases}$$

- heuristic stopping rule: STOP if  $NLP(y^j)$  gets worse

AIMMS has version of outer approximation

## MINLPBB: (Leyffer, 1998)

**Features:**

- AMPL branch-and-bound solver
- variable types: integer, binary, SOS1
- variable selection: integrality, priorities
- node selection: depth-first & best bound after infeasible node
- NLP solver: filterSQP  $\Rightarrow$  **feasibility restoration**
- CUTer interface available

## SBB: (Bussieck and Drud, 2000)

**Features:**

- GAMS branch-and-bound solver
- variable types: integer, binary, SOS1, SOS2, semi-integer
- variable selection: integrality, pseudo-costs
- node selection: depth-first, best bound, best estimate
- multiple NLP solvers: CONOPT, MINOS, SNOPT  
 $\Rightarrow$  **multiple solves if NLP fails**

**Comparison to DICOPT (OA):**

- DICOPT better, if combinatorial part dominates
- SBB better, if difficult nonlinearities

## Global MINLP Solvers

**$\alpha$ -BB & MINOPT: (Schweiger and Floudas, 1998)**

- problem classes: MINLP, DAE, optimal control, etc
- multiple solvers: OA, GBD, MINOS, CPLEX
- own modeling language

**BARON: (Sahinidis, 2000)**

- global optimization from underestimators & branching
- range reduction important
- classes of underestimators & factorable NLP  
**exception: cannot handle  $\sin(x)$ ,  $\cos(x)$**
- CPLEX, MINOS, SNOPT, OSL
- **mixed integer semi-definite** optimization: SDPA

## Online Tools

### Model Libraries

- MINLP World [www.gamsworld.org/minlp/](http://www.gamsworld.org/minlp/)  
scalar GAMS models ... difficult to read
- GAMS library [www.gams.com/modlib/modlib.htm](http://www.gams.com/modlib/modlib.htm)
- MacMINLP [www.mcs.anl.gov/~leyfffer/macminlp/](http://www.mcs.anl.gov/~leyfffer/macminlp/)  
AMPL models

### NEOS Server

- MINLP solvers: SBB (GAMS), MINLPBB (AMPL)
- MIQP solvers: FORTMP, XPRESS

## COIN-OR

<http://www.coin-or.org>

- COmputational INfrastructure for OPerations RResearch
- A library of (interoperable) software tools for optimization
- A development platform for open source projects in the OR community
- Possibly Relevant Modules:
  - OSI: Open Solver Interface
  - CGL: Cut Generation Library
  - CLP: Coin Linear Programming Toolkit
  - CBC: Coin Branch and Cut
  - IPOPT: Interior Point OPTimizer for NLP
  - NLPAPI: NonLinear Programming API

## Conclusions

MINLP rich modeling paradigm

- most popular solver on NEOS

Algorithms for MINLP:

- Branch-and-bound (branch-and-cut)
- Outer approximation et al.

“MINLP solvers lag 15 years behind MIP solvers”

⇒ many research opportunities!!!

Part V
